I've got a question that I hope someone can answer. In studying the ARRL Antenna Book it says that a folded dipole is a balanced antenna. It also says that a balun should be used when feeding a balanced antenna with an unbalanced line like coaxial cable. I think I've got that all right so far. My question is this. With a Decible Products antenna which has folded dipoles, should a balun be used between the antenna & the feedline? What are the problems if no balun is used?
I'm relatively new to this stuff so any info will be appreciated.
Thanks
Jim

1449. 10-80m Multiband w/300ohm twinlead?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-08 05:47:50 UTC
From: poofbutt@eudoramail.com

Source record: 181366

Hi Guys!

I have a good working 40m (~66 foot) flattop dipole at about 30' fed with 75 ohm CATV coax presently.

What I would LIKE to do, is run about 135 feet of dipole, bending the ends down (90 degress) a bit in the trees that hold 'em, and feed it with 300 ohm coax and have it work decently on all bands 10-80m.

My rig is a Kenwood TS530S, and it the internal tuning circuit can handle (match?) loads from 25-200 ohms. The rig's actual input antenna load can handle 50-75 ohms.

I am thinking I will need a 4:1 balun to get the antenna load within range of my rig. (300 to 75 ohms) Does this sound correct?

Does anyone know if the 530S can handle broad enough tuning to work with this type of multiband dipole?

Also, is there a specific length of twinlead that would be best/optimal to use for best all around coverage?

I have a 3 element tribander (A3) for 10-15-20, so basically the multiband dipole would be for listening on those bands, but 12-17-40-80 would also be for xmitting.

Much thanks - Ed - KF6YKM - Southern California

Scott,

A j-pole is a good antenna for VHF, and easy to make. If the tubing is too visible, I suggest contructing your j pole using either 300-ohm TV type twin lead (available at Radio Shack) transmission line, or even better 450 ohm window-line (like twin lead, but black, twice the width, and with little windows cut out of the center of the insulation. THis is easy to hide, you can even tape or glue it to some non-conductive surface (the side of the house for example) and paint over it.

Snorky,
I think you would have better luck using a tuner, a 4:1 balun
with 300 ohm twin lead won't get the impedance in a usable range
on all the bands you want.
A 130' doublet fed with ladder line is the 'classic' all-band
antenna, but most descriptions assume your going to use a tuner.
They do work though.

Must be hundreds of them! A couple of things to do is to
make sure the pole the rotor is mounted on is ~firmly~ anchored
to the 'T'-pole, and not too tall above the 'T'-pole. The mast
from rotor to antenna needs to be fairly short too. There's a
pretty good amount of torque developed by the rotor, and can
twist the pipe/pole/mast it's mounted on, if it isn't secured
well. Guying above the rotor is a real 'pain', so the mast needs
to be short between rotor and antenna.

Jeff,

You certainly could try the off-center feed. Further info was published in the ARRL Antenna Compendium, Vol. 3, pp 66-75. Both this paper and the one I believe you reference have designs for 4:1 ferrite loaded baluns. The half-wave balun you first inquired about would certainly work as well, but it is a single band solution.

There was an article in the old Ham Radio Magazine that did an analysis of the half-wave balun. I have it somewhere but my retrieval "system" is less than good, so I'm not sure I can find it quickly. As I recall, tinkering with the impedance of the half-wave section had some desirable effect on the operational bandwidth. (Your 75 ohm may be just the ticket.)

> --
> 73, Cecil, W6RCA http://www.mindspring.com/~w6rca

Method-of-moments modeling programs like those based on MININEC or NEC don't make any assumptions about current balance. The only assumption they make is that the current varies in a particular manner over a segment or "pulse". In MININEC, the current is assumed to be constant over the "pulse" which extends from the center of one segment to the center of the next. In NEC, the current is assumed to have the shape of a piece of a sinusoid over a segment. The programs calculate the self and mutual impedances of each segment or "pulse" relative to every other one, then using the voltages produced by the sources, calculate the currents on each segment or "pulse" using Ohm's law. It's certainly possible to model both imbalanced antenna and feedline currents with these programs. The main limitation to accuracy is the uncertainty about the path common mode feedline currents take to the ground in the actual installation.

Thread:

I worked in downtown Atlanta for a number of years and my office window looked right out over the GA Tech campus at about the 40th floor level.

I always wondered when I looked at the midtown AM antenna of WSB...

WSB's AM clear channel MW tower is in midtown Atlanta. What are the EMI levels a few blocks away at several hundred feet above sidewalk level?

In some of the local Atlanta skyscrapers, say the BellSouth tower or NationsBank tower, etc... the folks sitting at their office desks 8 hours per day 5 days per week probably feel that they can almost reach out and touch that 50 kW clear channel MW antenna.

Just wondering?

I think you may have that a little 'backwards'. The ARRL never
had any say in what modes are used in which portion of the bands.
They ~suggest~ bandplans, but that's certainly not binding.

Source record: 181286

Well Steve,

I assume you enjoyed your last (abusive) post: it ended up twice on AOL anyway.

READ my info carefully. I said that your design does not work as you describe. This is from my EXPERIENCE--as I said-- with those spirals, which often are the 'base' antenna I am ask to improve upon in RFID applications at Fractal.

I did not imply that you should take that personally, but as a motivation to re-check what you did.

It is impossible to get a high radiation resistance at the current max without duplicate current max's. See what happens to yours. Then notice how much wire you've got; isn't it of order 5 or 6 wavelengths? The MI2 uses about 1 1/2 waves of wire.

That's all I will say: I graciously offered to look at the file and give you feedback--AS ANY PROFESSIONALY WOULD DO TO ANOTHER. Because you are being abusive, I will not do so now, as I feel that you, as president of Cushcraft, are not acting as a professional but as a competitor.

I will honor your submission under the rules should you have something to submit, but further keep in mind that if we are to entertain the possibility that you DO have a 'winning entry' then what kind of person are you for libeling someone about to give you $1000?

As for the MI2 file: I have, in the past, given this file out on: NEC-LIST (with a free video also); Rec.radio.amateur.antenna; and fractalantenna@egroups.com. Now I only honor requests from those on the fractalantenna reflector, and certainly none from those who abuse.

So basically the answer is that I do not consider you a colleague, or one evincing professional behavior and will not honor your request, should it come from the proper channel.

Next time, before you close doors, find out the size of the building.

Chip N1IR

The levels in various immunity standards are approximately 3 V/m. The levels
in the RF exposure standards are >= 27.5 V/m. It is very difficult to
correlate RFI and RFX issues with 20 dB of difference between the two.

Wayne GHrauel wrote:
"Live and learn."

Mobile whip springs are not loading coils. Inside should be an intact strap to short out the spring. Bend the spring over and have a look. If the shunt is missing or broken the spring should be discarded.

A 5-foot whip is too short to be a quarter-wave at 10 meters without a loading coil. It is near 1/4-wave at 6 meters.

108 inches is 9 feet or about 2.74 meters or about 1/4-wave at 11 meters. A whip this length may actually be too long in the 11-meter band. High voltage at the tip of the antenna actually increases its apparent capacitance. This effect depends on the length to diameter ratio of the wire, but the usual rule is to shorten a whip 5% for "end effects". This makes the 11-meter whip 102 inches long.

A 5-foot whip will need a loading coil to resonate at 10 meters. You could also consider a large capacitive hat to resonate the whip at a lower frequency. The hat doesn`t have so much resistance to lower the efficiency of the whip as a coil does. A combination of loading methods can be used. You can check for resonance with whatever instruments you may come by.

When resonant at 1/4-wave, the impedance will not likely be too close to 50 ohms. A 1/4-wave vertical is 1/2 of a 1/2-wave dipole. The other half of the antenna is supplied by its image in the ground, car body, ground plane, or what have you. The dipole in space has 75 ohms impedance and 1/2 of that is about 37 ohms. the environment of the whip will shift its impedance also and it may well be less than 37 ohms. You may consider 37 ohms close enough to 50 ohms and that`s just fine too.

Some would prefer the convenience of a short loaded whip. Most CBers do. That`s why you see those little whips emerging from various sizes and shapes of coils. It isn`t as efficient as a full-sized whip but may be plenty good enough.

Best regards, Richard Harrison, KB5WZI

"10 dB between those two values."

That`s the trouble with using "field strength" to mean power per square meter and also volts per meter.

Ed was using the ratio between two volts per meter values which were about 10 to 1. Thus, Ed Hare correctly called it a 20 db difference where the voltage ratio is 10 and the power ratio is 100. When you multiply the volts by 10 you automatically multiply the current by 10 also, in a linear resistance, and thus the power is multiplied by 100 times.

Roy, Since all elements of a G5RV dipole antenna model are symetrically balanced, how can EZNEC possibly report imbalance? The argument is not whether EZNEC *can* handle imbalance. The argument is whether EZNEC can possibly generate imbalance in a perfectly balanced antenna system.

Whats Up DOC.... Sorry couldn't resist :-)

Tricky Dickys still sell the station master, they were and still are made by Mobile One Australia. If you want to home brew one try http://www.wildnet.com.au/users/amateur_radio/ click on the buttons on the Icom when it loads for antenna calculators (4th and 5th one from the top), there is one there for a 1/2 wave and a 5/8 vertical.

Failing that why not just go out and buy a second hand station blaster... if your shrewd you can usually pick them up in the trading post for $25 or so. The only difference between 10 and 11m is the length... just shorten it down a little... the tap doesn't usually get touched at all.

> N3TNS

Well, what you have is probably a CB antenna, but there is nothing
wrong with using it on 10 Meters. 11 Meters is close enough
to 10 so that most any CB antenna can be adjusted to work well.
I have one on my house and on my car.

The one on my house is effectively a vertical dipole that's
up about 25 feet. It does an excellent job.

The one I use on my car is a little 3 foot whip with a
loading coil in the magnetic mount base. I purchased it at
Radio Shack. Using my HTX-100, and the antenna on the back
of my 1989 Firebird, I have no trouble talking to the mid-west
or the east-coast, from Phoenix. I even did some testing at
the 5 Watt level with some stations in Virginia, while I was
driving home from work. I was a little low on the S-Meter,
but there was still solid copy.

The two big shiny coils, on your antenna, are just springs.
If you bend them over you should find a ground strap inside
shorting out the whole thing. If that strap isn't there, or
the strap breaks, that spring can cause lots of hash and
noise. If you keep them, make sure the ground strap is good.

But before you throw the whole thing away, I would suggest
borrowing a Antenna Analyzer from a friend (something like a
MFJ 259) and find out what the antenna is actually set up for.
It may be quite usable with just a little tune up. However,
don't expect the SWR to be flat from 27 to 30 MHz. Short
whips are a little narrow banded so just optimize it for
the area you need. Usually the only adjustment would be the
length of the whip. The Antenna Analyzer will tell you very
quickly whether the whip is to short, or to long, or just a
piece of junk.

Other posters have suggested that the optimum is a 108 Inch
whip, and they are probably right. If you can't make your existing
antenna work, it would be a good avenue to persue.

Good Luck

I assume that the "300 ohm coax" is a typo. There does exist shielded
300 ohm line called TwinAX. Are you talking about that?

> I am thinking I will need a 4:1 balun to get the antenna load within
> range of my rig. (300 to 75 ohms) Does this sound correct?

The impedances you are likely to encounter may range as low as 20 ohms.
A 4:1 balun will try to take 20 ohms down to 5 ohms. On the other end,
you may encounter 4K ohms which the 4:1 balun takes down to only 1K ohms
assuming it can handle the 4k ohm load. In addition, you may encounter
something like 2000 +j2000 ohms which the 4:1 cannot handle very well.
Your idea of using a limited range tuner with an antenna like the above,
is heartburn city. A wide-range link-coupled tuner is best for this
antenna.

> Does anyone know if the 530S can handle broad enough tuning to work
> with this type of multiband dipole?

A subset of the method I use for matching would be ideal for your
application. Choose a feedline length for each band that will
resonate the antenna system in the middle of the band and then
use your built-in tuner to cover the whole band. I use knife
switches mounted in my ham shack window to tune all the HF bands
with no antenna tuner required at all.

> Also, is there a specific length of twinlead that would be
> best/optimal to use for best all around coverage?

Follow the links on my web page to my All-HF-Band-Antenna to get
an idea of what is necessary to accomplish what you are trying to
accomplish. What will work for you is a subset of what I have done.

Jim wrote:
> What are the problems if no balun is used?

Good engineering practice calls for a balun (BALanced to UNbalanced) function at every balanced to unbalanced transition. Assuming a coax/twinlead junction, a properly functioning current balun will keep common mode currents from flowing on the outside of the coax and will ensure that the differential currents in the twinlead are balanced thus preventing more than a negligible amount of feedline radiation and conducted common mode currents. Whether feedline radiation and conducted common mode currents are an appreciable problem depends on the application and the user's tolerance level. My tolerance level is low.

Dear Dr. Cohen,

27.7/3 is a ratio of 9.16.

dB is 20 log ratio when dealing with voltage.

20 log of 9.16 is 19.23.

Please tell me what the under educated masses are missing, Dr. Cohen.

The ARRL chose to not ask for a segment. Prose Walker told me the FCC would have no problem granting one when the band was restored, if the ARRL asked.

In my present set up I route the coax THRU the boom.
Most books say' hang' the feed' which also has draw backs
But if the feed lines can affect calculated patterns or
antenna performance on the increasing used results of computor
programing such as EZNEC, then maybe it is time for all to rethink
or re-evaluate the implications of feed methods and construction
Possibly some could share their thoughts.
Appreciate the input Roy

Chip has some odd notion the more wire you pack into a given spatial
volume, the higher efficiency and radiation resistance is.

He doesn't know light bulbs and electric heaters use his theory for
increased radiation resistance....of course it's mostly in the form of
thermal radiation.

Reg Edwards wrote:

[description of how to model the transmission line common mode deleted]

> But if you are interested in the input impedance of the coax
> it will have to be measured or calculated separately.

EZNEC has the ability to model lossless transmission lines. The model treats transmission lines as lossless two port devices obeying the (lossless) transmission line equation for specified characteristic impedance and electrical length. Each of the two ports are placed in series with a wire segment.

Used in combination with the method for modeling the common mode behavior of the transmission line Reg described earlier in the thread, the transmission line model will provide realistic feedpoint impedances and field strengths for many practical amateur installations.

The hard part is determining how to model the ATU and station ground system. Link coupled ATU's (i.e.. Johnson Matchbox) are easily modeled as open circuits for the transmission line common mode. The more common unbalanced T tuners require knowing more about the station ground then is usually possible.

I actually did an article on thsi years ago....

The SO 239/PL 259 combo is good up to about 400MHz. It was originally
a military connector and became standard for Amateur Radio and CB.
This connecotr's impeadence CHANGES with frequency though!

All of you HF frequencies are unaffected (basically) from this
connector. This includes CB too. They are easy to install and work
well UNTIL you get to higher frequencies.

The N-Connector on the other hand has a CONSTANT IMPEDANCE up to the
Gigahertz range. You buy either a 50 ohm or 75 ohm connector. The
N-Connecotr also has a gasket to seal out water/moisture! It is clearly
a superior connector but is a little harder to install.

If I remember right, the UHF (SO 239/PL 259) connector can handle more
power (watts) but don't quote me on this.

The BNC is a "Bayonet N-Connector" and also has a CONSTANT IMPEDANCE
but lacks the seal.

I have converted most of my equipment to either BNC or N ancluding my
antennas. The better antenna companies offer N-connectors on their
HF antennas.

Yaesu and Kenwood produced radios that used N-Connectors for 440MHz and
above for a reason. Remeber the UHF connector is only good to 400MHZ and
does NOT garrantee a constant impedance! This causes a mis-match resulting
in higher SWR. Its like having a 75 ohm feedline hooked to a 50 ohm
feedpoint.

Now to answer your question...

You find quality connectors on quality cable. You buy the better cable for a
reason! Why ruin that with a substandard connector. Do it right the first
time. Besides, why would you want a higher SWR even befor you hook it to the
antenna due to cable/connector mis-match.

Most HF stations do NOT run Heliax. You find these on long runs and VHF and
above. Especially repeaters where you want a CONSTANT IMPEDANCE in your
feedline and antenna.

For HF, regular coax and a UHF connector is fine.

Dino...K6RIX

>Ok, then I'm curious...
>Why is it that UHF connectors are not standard on real thick cables like

>Andrews 1/2" and up? I see that N type is standard when using heliax and
>thicker cables up to a point.

Actually Chip, the non-fractal design that I ran on NEC has a total wire
length of about 1.51 wavelengths, not the 5 - 6 wavelengths that you claim
without even seeing the design or the model. As I stated previously, it is
my technical opinion that the lowering of the resonant frequency is more a
function of the total wire length than the Fractal shape. Note that my
non-fractal design and the MI2 have similar total wire lengths.

> That's all I will say: I graciously offered to look at the file and give
you
> feedback--AS ANY PROFESSIONALY WOULD DO TO ANOTHER. Because you are being
> abusive, I will not do so now, as I feel that you, as president of
Cushcraft,
> are not acting as a professional but as a competitor.
>

I was not trying to be abusive at all. You started a very public technical
discussion on a Fractal antenna design. You then publicly asked everyone on
the NG to see if they could come up with a design offering similar
performance. You even offered to pay people $1000 if they were successful
in their efforts. You may not realize this but doing so as a representative
of Fractal Antenna Systems, you have created a legally binding contract that
your company must honor. You should also review your e-mails and note that
you asked me personally to use my Ph.D and experience to take the "Fractal
Challenge".

Being personally interested in the claimed performance of Fractal antennas
for some time, I decided to run a quick non-fractal design on NEC (on my own

personal time). I summarized the results of my NEC model and your response was that I made a mistake in my calculations. I still believe that your off the cuff response was presumptuous and arrogant, considering that you did not see the design.

As far as Cushcraft is concerned, this is not a competitive issue at all. In my NG posts, I did not mention my affiliation with Cushcraft. It was you who brought up the subject of my Cushcraft affiliation. I did not present my design as a representative of Cushcraft Corporation. I presented it as Steve Best in response to your direct personal request of me. Cushcraft Corporation has no intension of manufacturing or selling my design. I have not and will not publicly compare the performance of your products against any of the Cushcraft products. In fact, in my posts to the NG, I explicitly stated that I do not doubt the claimed performance of the MI2 antenna.

Personally, I would prefer that you not mention my Cushcraft affiliation again.

>
> I will honor your submission under the rules should you have something to
> submit, but further keep in mind that if we are to entertain the
possibility
> that you DO have a 'winning entry' then what kind of person are you for
> libeling someone about to give you $1000?
>

The statements made in my posts to the NG were not "libeling". Technical professionals have differing technical opinions all the time. If you publish a technical opinion in the open literature or in a public forum, you will find that other technical professionals may disagree with you and in fact may consider your technical opinions to be incorrect, invalid and just plain wrong. Another person stating that they disagree with you or that they believe you to be wrong is not libelous behavior. It's part of the risk you take when publishing data and stating technical opinions based on that data. I did not call you a liar, I did not say that you falsified technical data, I did not say that your designs do not work as claimed. I simply disagree with some of your technical opinions regarding the claim that any enhancements in antenna performance are solely a result of the Fractal geometry. No US laws preclude me from having this technical opinion nor do they prevent me from stating it.

Actually Chip, your statement: "I said that your design does not work as you describe" is more libelous than any of the statements I made.

>
> So basically the answer is that I do not consider you a colleague, or one
> evincing professional behavior and will not honor your request, should it
come
> from the proper channel.
>
> Next time, before you close doors, find out the size of the building.
>

> Chip N1IR

I stated some technical opinions and stated the results of a NEC model. You responded by claiming that my opinions were incorrect, speculative and that my analysis must have been a mistake and that my design could not work as I claim. You're the person burning the bridges with everyone you come in contact with. I guess you just added me to your list.

I would prefer to keep further conversations focused on the technical issue, so I hope we can cease with this foolishness. Also, please do not mention Cushcraft again.

73,
Steve VE9SRB

The BW you have is probably typical, although you did not say whether
this was measured at the antenna or in the shack. . But perhaps you
should be more concerned with what the gain and F/B are doing over the
BW you desire. VSWR is not a very good indicator of antenna performance.

Hi Jim-

A folded dipole is a balanced antenna normally either fed with balanced feedline of the same impedance, or fed with coaxial cable through a 4:1 impedance transformer (which may also function as a balun).

A regular wire dipole is also a balanced antenna, but has a lower feedpoint impedance that allows it to be fed directly with coax. Coax cable is unbalanced and the outer part of the shield becomes a "third leg" of the antenna when a balun is not used to prevent this condition from happenning. How much energy the "third leg" steals from the rest of the antenna and radiates depends on a number of factors, but its length is usually a major determinant.

Many people, and even the ARRL, feel the importance of using a coax-fed balun on a dipole is grossly over-rated. Many also feel the use of automobile seatbelts and motorcyle helmets are over-rated, as well (until they split open their head, anyway).

You might get by forever without a balun. Or, you might find you can't do E-mail and transmit at the same time without getting knocked offline. You might find your transmitter gets into the phone--or sets off the security alarm. You might find you can't use the speech processor without getting RF feedback on your audio. You might even get a little "tingle" from RF on a particular band when you key-down on CW. So, if you're a curious guy, don't use a balun--who knows what you might find? However, if you don't mind being bored, and if you advocate using good engineering practices when setting up your station, by all means--use one!

Source record: 181316

This is a problem with statistical studies, in general:
people assume, when a statistical anomaly exists,
that there must be a correlation to something, even
if they cannot determine what that something is.
Why does a study show that there is a greater
percentage of leukemia in group A vs group B?
Because (assuming it is accurate) there are more
leukemia cases per unit population in group A
than in group B - the statistics are correct. But
then the error occurs, based on the assumption
that there is something common to group A that
is not common to group B. So we go merrily
off looking for the causative common denominator,
and don't question the initial assumption that there
IS a causative common denominator. That assumption
is reinforced by the statistics that show a common
denominator on the results side.

In the leukemia study of California hams, we assume
there might be a correlation to RF and investigate
that. Or we assume there might be a correlation to
employment in the electronics industry and
investigate that. Or a correlation to agricultural
chemicals and investigate that. And so forth -
that's the nature of statistical studies. They start
out with assumptions that some correlation exists.
And, clearly, in some cases statistical studies are
right. That lends more weight to the assumption
that a correlation must exist. And of course, there
is a further assumption that whenever a correlation
does exist, it can be revealed by a statistical study.

Where does that lead us? Well, perhaps to a bad
place. Take the commonly accepted idea that
exposure to too much sunlight leads to skin cancer.
Statistics seem to bear this out, from what I've
read. For the sake of this discussion, let's assume
that it is true. Ok, why is it that some people who
are exposed to far more sunlight don't suffer
skin cancer than those exposed to less sunlight do?
Well, we still say exposure to sunlight is *a* factor.
Then we (statistically) discover some other factors -
exposure to certain chemicals, heredity, diet, etc.
We now have a range of answers to the question,
instead of a blank slate with NO answers. How

many researchers are now more interested in
investigating something else because we have
those answers? And, does the fact that they
investigate something other than the cause of
skin cancer lengthen the amount of time it
will take us to determine the REAL underlying
cause, if one does exist? Suppose, as some
believe, there is a virus as the underlying cause.
If the virus were detected and treated or if there
were a vaccination against it, no amount of exposure
to sunlight or chemicals, or inherited defect or
whatever would cause skin cancetr, according to this
belief.

Don't get me wrong - I'm not claiming to know
any answers on the exposure to RF being damaging
or on the validity of the statistics involved. I am
only trying to point out that statistical studies
are based on assumptions at the very core of the
process - and that the results of those studies
can possibly be not only incorrect, but counterproductive.

How were you measuring the line parameters? I assume you were measuring input impedance; was the far end opened, shorted or terminated with a 75 ohm load?

> At
> "low" frequency the surge impedance (Z0) was about 75 ohms, which, as
> the frequency was raised, proceeded to spiral around the 50 ohm center
> of the Smith chart.

Sounds like the transmission line had one or more impedance bumps resulting from mechanical damage or corrosion. A good lab project for EE students is to take the input impedance (S11) data and use it to quantify and locate the transmission line fault. The procedure goes something like:

1) Collect a vector of suitably spaced input impedance measurements.
2) Convert measurements to reflection coefficients normalized to nominal line impedance (assumed or determined from data).
3) Transform into the time domain using the discrete Fourier transform.
4) Determine velocity factor by locating reflection from far end.
5) Determine the fault location and reflection coefficient.

The experiment can be compared to direct time domain measurements using a pulse source and oscilloscope.

> Yes, surge impedance can become reactive.

How did you derive the surge impedance from the data? The surge impedance is complex (Zo = sqrt((R+jwl) / (G+jwC)) of course, but tricky to estimate accurately from input impedance measurements. The technique described above only works well if the transmission line has low distortion (R/jwl approximately equal to G/jwC) over the frequency

range in question.

Hello All,

I am looking a antenna parts supplier for gamma matches for 2 meter & 70 cm. I am going to build a Oscar antenna like the Arrow, but with higher gain. Can anyone recomend a source. I don't want the hassle of trying to build my own gamma matches.

Thanks,

Jeff

1509. Re: How to calculate wire equivalents of balanced feeders for EZNEC

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-08 17:40:14 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <39B9247E.C6C9593C@eznec.com>
Source record: 181375

Balance isn't a function of the antenna as much as it is how it's fed. For example, a dipole fed with symmetrically-placed twinlead can easily be an unbalanced system. Just take one conductor of the twinlead and plug it into the center conductor of your rig's SO-239 output connector, and connect the other to the rig's chassis. This will produce unbalanced (common mode) currents in the two feedline conductors and in the two halves of the dipole. You can simulate this with EZNEC by modeling the dipole and feedline (which has to be modeled as two wires, not a transmission line model), putting a source across the feedline at the bottom, and then running a wire from one of the feedline conductors to ground. This added wire represents the path to ground from the rig's chassis.

Another way to create unbalanced currents in a twinlead-fed dipole is to place the feedline non-symmetrically with respect to the antenna. If you do this with EZNEC (again using two wires for the feedline), you'll find common mode current on the feedline and unbalanced currents in the antenna halves, just as you do in a real antenna.

Placing the source across the feedline at its input end, and no other connections at that point, simulates a feedline fed with a perfect balun or a truly balanced system such as a link coupled tuner. It's an appropriate model only if this is what you're trying to simulate. If you have this kind of system, and if your feedline is placed symmetrically with respect to the antenna, the currents on the antenna halves will be balanced and there won't be common mode feedline current. And the EZNEC model will show this.

And, of course, you can simulate a coax cable, including the path along its outside, by using a combination of a transmission line model and a wire. The technique is described in the EZNEC manual.

In most simulations I've done, feedline current doesn't have a major impact on the main antenna lobe. (A notable exception is VHF ground planes and J-poles, where a worst-case feedline current can drop the signal intensity at the horizon by a couple of dB.) However, it could certainly trash a beam or phased array's front/back ratio, since relatively little radiation is required to do that. This is especially true if you're shooting for very deep nulls.

In my opinion, there are other compelling reasons to use a balun, which have been articulated in this group and elsewhere. But whether the effect is worth the effort is strictly a judgement call, as a number of people have pointed out, and some choose to use one and some not.

signal
> drops out. Thanks.

Well I would not consider 1W a small signal at 2.4GHz, however,
any form of parabolic dish could be used at this freq with a dipole mounted
at the focal point.
a dipole of around 3" could be used you would have to find the focal point
of the dish.
f = D^2/16c
so the focal point of the dish is equal to the Diameter of the dish squared
divided by 16 times the depth of the dish at the centre.
so a 1ft diameter dish with a depth of 2 inches at the centre would give
144/16x2 = 4.5 so the focal point would be 4.5"
remember that this is the focal POINT so you would have to bring your dipole
in towards the dish.
this would give you a fair amount of gain and if you fit a pre-amp would
really hot things up.

From what other comments have been made to your request some seem a little
negative, which does not supprise me with today's radio hams.
As far as I am concerned by increasing the sensitivity of the receive side
would not break any licence only if you increased the transmit side which
could cause interference to other band users.
However, I do not live in the U.S. so do not know your laws too well, but
using common sense I cannot see a problem with what you are asking.

And besides if it helps to catch criminals there that's great by me.
hope this helps a little.
cheers Mark

The car body is generally used a the counterpoise, or ground plane, for the antenna. The optimum place for the antenna would be in the middle of your roof. Mounting it on the rear bumper may make it a little directional. That's not a problem when you are traveling down a nice straight highway, but on winding country roads it could cause a lot of signal fading as your car turns.

You really want as much of the antenna in the clear as possible. A bumper mount tends to hide some of the whip.

With the antenna on my car, the rear mount didn't seem to cause a direction problem. As long as I was headed in the right general direction, the signal stayed solid.

I'm not to sure what you mean by "grounding issues". When I mounted my rig under my dash, I grounded the rig through the power cables only. The dashboards these days are all plastic. The antenna gets its ground through the coax to the rig. The magnetic antenna mounts are all plastic on the outside and don't actually make electrical contact with the body.

The RG-58 cable then just runs down under the carpet and out the rear hatch. The hatch just closes on the cable but doesn't seem to harm it. A better way would probably be to bring the wire out through a hole in the bottom of the trunk. But this way has worked for years.

Some people have a lot of problems with ignition or alternator noise, but my car seemed to be pretty clean. If you do have noise problem you may have to resort to hash filters or other fixes.

Martin

1516. Re: How to calculate wire equivalents of balanced feeders for EZNEC

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-08 18:00:36 UTC
From: CAM <cam2338@bigfoot.com>
Message-ID: <39B92944.5159E5DB@bigfoot.com>
Source record: 181379

Roy Lewallen wrote:
> Balance isn't a function of the antenna as much as it is how it's fed.

Again, the question is not how bad an antenna design can be goofed up, it is: Does a G5RV *ALWAYS* have feedline radiation? I contend that a well designed, properly installed and fed G5RV has negligible feedline radiation and the model of such a well designed, properly installed and fed G5RV will show negligible feedline radiation. I contend it is a myth that part of the G5RV radiating elements have been folded back into the transmission line thus causing feedline radiation.

The "springs" he is talking about are not at the base of the antenna
and do not have a strap across them to short them out. They are very
large inductors. The first one is about 2 feet from the base and the
second one is about 6 inches above the top of the first antenna. They
are used to load the 5 foot antenna for use on 11 meters.
>
> A 5-foot whip is too short to be a quarter-wave at 10 meters without a
> loading coil. It is near 1/4-wave at 6 meters.

Thats right and the reason for the very large inductors that look like
springs.
>
> 108 inches is 9 feet or about 2.74 meters or about 1/4-wave at 11
> meters. A whip this length may actually be too long in the 11-meter
> band. High voltage at the tip of the antenna actually increases its
> apparent capacitance. This effect depends on the length to diameter
> ratio of the wire, but the usual rule is to shorten a whip 5% for "end
> effects". This makes the 11-meter whip 102 inches long.

The Radio Shack whip is 102 inches long and with the heavy spring
added to the base makes it 108 inches long. As these antennas are
mounted to a bumper and some part of the whip is close to the metal
body, capacitance added to the system will require it to be just a
little longer than required. This also brings the match impedance up a
little more than the 37 ohms for a vertical mounted over a ground
plain. Also as the ground plain extends in only one direction at the
mounting point at the rear bumper this also tends to get the impedance
closer to 50 ohms.
>
> A 5-foot whip will need a loading coil to resonate at 10 meters. You

methods
> can be used. You can check for resonance with whatever instruments you

> may come by.

The people that build this antenna have all kinds of stuff hang on it. None of it really improves the antenna but causes it to look impressive to people that know nothing about antenna's. They make a "beam antenna" that takes the place of the second inductor. It is really only a capatiance hat but there is about a 3 foot boom on it a 5 elements with a 6 radial capatiance hat on the back of the boom.

> When resonant at 1/4-wave, the impedance will not likely be too close to

> ohms close enough to 50 ohms and that`s just fine too.
>
> Some would prefer the convenience of a short loaded whip. Most CBers do.

That is another problem with this antenna. It must have the inductors mounted high and away from the car or truck body to keep the stray capacitance at a constant level. You really need to see one of these things to understand the problems this antenna has. You end up with the top of the antenna higher than a 102 inch whip mounted to the bumper.

> That`s why you see those little whips emerging from various sizes and

This might be what we've been waiting for.

This, plus incoherent measurement techniques, could explain why
fractals have extra gain and why that data has been measured and
confirmed by Dr. Cohen.

> waves of wire.
>

In "re-checking" my design, I modified the parameters a bit to change the resonant frequency and resonant resistance. The model is comprised of 964 wire segments and was run on NEC4. Geometry was checked with GNEC (also running a NEC4 engine). Here is an overview of the results:

Resonant Frequency: 13.765 MHz

NEC4 Calculated Impedance: 40.87 + j0.82 ohms

2:1 SWR Bandwidth wrt 50 ohms (no matching): 1.73%

Antenna Maximum Physical Aperture: 0.122 wavelengths by 0.133 wavelengths

Total Wire Length in the Antenna: 1.564 wavelengths

I could trade off wire length, aperture size, resonant frequency, resonant resistance, bandwidth, etc but did not want to spend anymore time on this one.

BTW - This design occupied about 5 minutes of thought procees, not years of research. Suck it up and send the check. (Now that's abusive)

73,
Steve, VE9SRB

Steve- the real number of posting persons using the name 'Fractenna' is not known. However, among the signatures you are referring to, the real person is Nathan L. Cohen, who has a Ph.D., and is licensed as N1IR. He signs as Chip, (apparently a long-standing nickname) when he is being buddy-buddy and palsy, as NC on many occasions when the situation is ambiguous, as Nathan Coven, Ph.D. when he is being stern with the peasants. He also uses that when he threatens lawsuits and other retribution for people who do not show him proper respect.

IN addition, there are other names used. One is Phil, for which there is apparently a real counterpart, used usually when the entity wants to be vulgar and insulting- Cohendog (really!) when ridiculousness is called for, but the sacred names are not to be used, and several others, invoked when he wants to pat himself on the back, or ask a question that no real person has asked, so he can pontificate. AOL lets subscribers use many names, at will.

TRying to keep up with it is futile- just read, and chuckle at the fantasies created by an especially puerile mind.

Message-ID: <8pbkq1$6nu$1@bob.news.rcn.net>
Source record: 181395

The following short quiz consists of 4 questions and tells whether you are qualified to be a "professional." Scroll down for each answer.

1. How do you put a giraffe into a refrigerator?

The correct answer is:

Open the refrigerator, put in the giraffe and close the door.

This question tests whether you tend to do simple things in an overly complicated way.

2. How do you put an elephant into a refrigerator?

Wrong Answer: Open the refrigerator, put in the elephant and close the refrigerator.

Correct Answer: Open the refrigerator, take out the giraffe, put in the elephant and close the door.

This tests your ability to think through the repercussions of your actions.

3. The Lion King is hosting an animal conference. All the animals attend

except one. Which animal does not attend?

Correct Answer: The Elephant. The Elephant is in the refrigerator.

This tests your memory.

OK, even if you did not answer the first three questions correctly, you still have one more chance to show your abilities.

4. There is a river you must cross. But it is inhabited by crocodiles. How
do you manage it?

Correct Answer: You swim across. All the crocodiles are attending the Animal Meeting.

This tests whether you learn quickly from your mistakes.

According to Andersen Consulting Worldwide, around 90% of the scientists they tested got all questions wrong. But many preschoolers got several correct answers.

It must be a Dusie!

Even so, sold as a CB antenna, it should resonate on the 11-meter band. If it adjusts as it should, it should work in the 10-meter band, with or without further adjustment, reasonably well. I`ve had good luck using 27 MHz antennas at 33 MHz. I sometimes did a little trimming.

I really appreciate the description of a very imaginative antenna. I don`t think the two coils give it "self similarity".

Best regards, Richard Harrison, KB5WZI

Cecil, when Z-matching it shouldn't be forgotten the
feedline Zo is just as important as its length. To reproduce
your results it is necessary to obtain a feedline of the
same impedance as yours. I recall you mentioning your Zo is
not the 450 ohms it says on the label.

Good to see you back in action.

Reg.

I already said this.

I also said that collisonal broadening makes such spectral lines absorb far
away from this frequency. Please check the relevant post.

If the G5RV is fed in a way that forces or allows only equal and opposite currents on the feedline conductors, then the feedline won't radiate. You're right in that there's nothing special about a G5RV which makes it more or less prone to radiate than any other symmetrical antenna like a dipole.

As a matter of fact, yes. Bandplans change, and the 'old' plans
never seem to be officially 'rescended'. Therefore there are a bunch
of 'out of date' operators out there that just have fits when you
transmit in a so-called 'allocated' segment of a band. I just 'LOVE'
to correct their misunderstanding. Bandplans should be by current
usage, not by someone's ideas who probably hasn't listened to an
active amateur band in years.

Forget the gamma matches at those frequencies. Look at some of the K1FO designs that use a beta match. It is simple to make those and they seem to work beter especially on the 70 cm band. You might have some problems finding the small hardline for the 70 cm stuff, but it is worth it.

Hello, Peter,

I assume a few blocks away is 300 feet. I assume that several hundred feet above ground level is 400 feet. EZNEC estimates that a 5/8-wave vertical with 64 half-wave radials over good ground will create an E field of 13 V/m at that point. Somewhat above the 3 V/m typical of RFI problems, but xx dB below the uncontrolled limit of 614 V/m.

EZNEC predicts that the field with 50kW applied would be at 614 V/m 1.7 feet from the antenna at a point 400 feet above ground. The antenna is 614.7 feet high in the model.

It must be habit for me to use the terms precisely; when I say field strength, I am talking about the electric or magnetic field. It would be quite incorrect to say a "field strength" of 1 milliwatt/square centimeter. So, in the far field, the electric and magnetic fields vary by 1/D while the power density varies as 1/D^2. Hams often say field strength when discussing power density, though, so some confusion is inevitable. (I sure did misuse the term before I had to learn more about it all to handle the RF exposure rules issue.) That is why I was careful to include the units as V/m, to help clarify why I used the 20 log (ratio) formula.

Sorry for any confusion.

I can make S N voltage measurements with pretty good accuracy if
needed, if I can con someone into giving me a carrier. I have accurate
modern selective volt meters that cover 160, and they are portable.
Someday when I'm smarter I'll build a loop and calibrate it, and then
I'll have a FSM without renting one.

Until then, all I can do is A-B tests. I don't know how many mV/m I
have, but I can measure a small change accurately. So I could do a
radial, and look at the slope of attenuation.

>Note that the angles are only good while the SNR is reasonable. SNR looks a
>bit low to me, but I did select residential noise instead of rural quiet.

I can measure noise, at 12 kHz, 3 kHz, or 100 Hz BW. But that isn't
the issue.

>I can't explain Tom's results through modeling, but he is a capable and
>qualified ham who has put a lot of effort into his testing. OTOH, the
>results I am getting appear to be consistent with what I would expect from
>theory for verticals and horizontal dipoles.

Another 160 op with access to a tall tower reports the same thing, as
I found out too late! On occasion there are reports of good-working
low dipoles, but they generally are not A-B tested against good
verticals.

The ringer for me was the ~.6 wl vertical. That thing pretty well
suppresses the high angle stuff, and still is great out 500 miles or
more. The dipole should be killer if the wave angle is 20-30 degrees
compared to that antenna.

BTW, I never say "dipole vertical", I always say 1-2 and randomly
switch around so 2 isn't always the same antenna. I also watch the
receiver, and know what the S meter means because I have a little
chart.

>for the number of segments, I think I was okay. I wonder if there are any
>other antennas nearby that are affecting the dipole more than the vertical,
>because the models say that the dipole should outperform the vertical almost
>all the time, sometimes by quite a bit.

At 300 feet or more high in the center, the dipole is reasonably clear. There is an 80 meter dipole at almost right angles, but it is 1/4 wl below the 160 antenna (about 150 ft high). Guy lines are insulated every 20 to 40 feet, closer near the tower. Fiberglass links at the tower.

I won't bore you with the details, but there are other antennas and towers scattered around. They are all over 300 or 400 feet from the tall tower. The important thing is I detune everything that isn't selected as the antenna being used to maintain patterns.

>Tom, is the SWR bandwidth of the dipole about what you would expect to see?

Seems fine to me. I can't really use the antenna outside the low end of the band, and the SWR on 80 meters is through the roof! I would expect less than an offscale reading on 80 if I had much feedline loss.

I have 300 feet of LMR 400 up the tower, with a choke balun of RG-8X. There's a choke at the bottom, about 50 feet of RG-8 foam "Superflex" cable. The feedline back to the tower is 7/8 inch heliax about 500 feet or so long. The antenna is #10 solid copperweld, with tarred nylon lines out maybe 700 feet or more holding the ends out.

You tell me. I'd sure like to use the tall tower! I installed it because the models told me the dipole would kick butt. What I find is I could have saved the money, I have vertical performance or less off the broadside and the vertical beats the dipole over 10 dB off the ends of the dipole!

Now a low dipole at 100-150 ft kicks butt 50-100 miles away. It's as much as 20 dB better at night than either the high dipole or vertical.

I think the wave angle is lower than people expect, but that's a guess. Right at sunrise, on some days, the dipole gets several dB better than the vertical. Only some days. Only at sunrise..unless we are having a nasty geomagnetic storm. Then the dipole works great, and that's maybe twice a year.

So is the wave mainly vertically polarized, the wave angle low, or does the vertical work better than the model shows?

Bandplans should be mandated by the FCC based upon proposals for rulemaking and
not "suggested" by a minority entity motivated by special interest. Who in
hell gave Dave Sumner and his band of merry men this power anyway? Fill me in!

Now, I *am* confused. The ratio between 27.5 V/m and 3 V/m, the figures I
used in my original post, is 19.24 dB. To what does the 10 dB relate?

> Now we have the usual imps trying to make me look like an idiot for it.

I'm certainly not trying to make anyone look foolish, just trying to make
sure we are discussing the same issue.

Thanks.

Thanks Roy, that's all I was saying in response to this original posting:

"Especially antennas like the G5RV where the dipole is active mostly on the
low bands and the *feeder starts to act as radiator on higher bands* cannot
be modeled this way."

My conclusion was that the person who wrote the test questions thinks more like a preschooler than a scientist. If that's the standard of "professionalism" used by Anderson Consulting, perhaps that tells us something about them too.

Yep, the stuff I use is actually 380 ohms so I need an SWR
between 15:1 and 3.8:1. With open-wire 600 ohm line, the SWR
needs to be between 24:1 and 6:1. This is almost always the
case with wire dipoles at least 1/2WL long at the lowest frequency
of operation. (The SWR on a *folded dipole* is too low for my
impedance transforming technique to match 50 ohms.)

Hi, Rick,

I think the power to make suggestions is given to Dave by the Constitution.

There are many people who feel that the only rules that amateurs need are "here are your band edges; have fun."

I am not one of them, but I do not believe that strict rules and regulations are always the answer, either.

1564. Improving 900Mhz reception

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-09 03:09:21 UTC
From: Jenni <Jenni_Mc@nonforme.Bellsouth.net>
Message-ID: <39B9A9E1.DDD0FE37@nonforme.Bellsouth.net>
Source record: 181231

Hi all,

I have a wireless(portable) data terminal operation in the 900Mhz range. It's operating indoors. In the location where I would like to place it, I can't get any reception. I can, however, if I move it to a different location or take it outdoors. So I'm assuming the area is somewhat shielded. I spoke with the wireless data service provider and they said that a 3db high gain 900mhz antenna could help me improve reception. However, they were not very helpful in explaining how to connect it or where to get it . In addition the terminal has no connections for an external antenna and the unit is sealed. If I break the seal to open it and monkey with the stock antenna, I am liable for damages with the company I lease it from. So my questions to the group are:

Does anyone know a way to connect an auxiliary antenna to the existing antenna so I can run it to an area with better reception? or perhaps a way to passively improve the signal?

Where can I find a 3db high gain 900mhz antenna? (Radio shack wasn't very helpful and there is too much info to digest on the web)?

Am I going about this correctly or can someone suggest a better approach (i.e. repeater? amplifier?)?

Thanks in advance for the response and sorry for the long post but I wanted to get out all the details.

-Jen

Hi Ed--

>I think the power to make suggestions is given to Dave by the Constitution.<

"constitution"?

>There are many people who feel that the only rules that amateurs need are "here are your band edges; have fun."<

I would expect my license and my operating rules to come from the same place. My license didn't come from Newington. Did yours??

>....I do not believe that strict rules and regulations are always the answer, either.<

Should the right-seat passanger in an aircraft be allowed to express his need to "make suggestions" by placing a hand on the yoke? I don't think so.

Which "constitution" do you speak of? The US Constitution, the League's Constitution, or the Tasmainian Articles of Confederation?? I'm confused.

I'd sure like to see two ways to get a license for HF operation.
One way would be to pass a code test and the usual electronics and
rules test.
The other way would not involve morse code, but would require a more
stringent electronics test.

At the risk of being called dumb or lazy, I've never been able to
master even 5 wpm, and given up long ago.

Maybe I'm being selfish, but I love to restore old tube type
plate-modulated gear as well as military radios, and I'd love nothing
better than to get the big old rig with the 4-1000 final and 304TH
modulators off the dummy and onto the nightly AM nets.. It's a real
commercial-duty showpiece, built by Durward J. Tucker in the '50's
(W5VU, bio article in CQ mag. April 1965, now a Silent Key).

I have no interest in using code, but I am interested in UHF, data,
TV, and spread spectrum in addition to boatanchor AM.

Thanks to the input from everyone in this thread, I finally fixed the reception problem I described.

This afternoon, I attempted to replace the cable that connects the antenna on the roof to my television set. I discovered that the antenna part that contains the "posts" to which the cable is attached was corroded and that it had separated from the rest of the antenna. I replaced the antenna and the cable and the reception problem disappeared. Parts of the old antenna fell off as I took it down. Obviously, those "elements" were also corroded.

Thanks to all of you for your help!!

Sincerely,
Steve Schlein

: So basically the answer is that I do not consider you a colleague, or one
: evincing professional behavior and will not honor your request, should it
: come
: from the proper channel.
:
: Next time, before you close doors, find out the size of the building.

Talk about appearing non-professional, as well as appearing to be an
arrogant ass.

You made an offer. The person provided prelimanary NEC results that appear
to meet your challenge. He has every right to submit that design to you,
and for you to honestly evaluate it and award the challenge amount if it
is indeed as described.

That would be true, whether the submitter is professional, arrogant, petty
or anything else. You did not set the condition that the person had to
kiss your feet before making the submission.

You are rapidly driving me to the point where I would refuse to purchase
an antenna from your company - even if it far outperformed every other
antenna in existance (which is highly unlikely as fractal antennas have
been around for decades). If they were so good, they would already be
in common use commercially.

: Has anyone seen an antenna and rotor like this mounted on top of a couple of
: lengths of conduit on the ground and pulled up next to the pole with a rope
: or cable ? Seems to me it could be done, but would like some feedback from
: anyone who may have tried to help find glitches in it before I try it (or
: not).

I haven't seen such a setup on conduit. However, you should be able to bolt a short length of 2" (or whatever size pipe the rotator base takes) to the pole. The mount has to be solid - not just raised with a cable.

If the rotator has bolt holes for mounting to a baseplate, it gets even easier - as you can bolt the rotator to the top of the pole.

In either case, to mount the rotator and antenna properly, you will need to either climb the pole or rent a bucket to get you up to the top of the pole.

I am assuming that it is your pole, and does not belong to the phone company.

Martin Meserve <meserve@my-deja.com> wrote:

: The car body is generally used a the counterpoise, or ground plane,
: for the antenna. The optimum place for the antenna would be in
: the middle of your roof. Mounting it on the rear bumper may make
: it a little directional. That's not a problem when you are
: traveling down a nice straight highway, but on winding country
: roads it could cause a lot of signal fading as your car turns.

That proported "directionality" is much over-rated. It is slight
to non-existant.

I have run a bumper mounted whip for decades, and have not noticed
any directionality at all - and I drive winding country roads all
the time.

: You really want as much of the antenna in the clear as possible.
: A bumper mount tends to hide some of the whip.

Correct. The point of maximum radiation is low, but does not seem
to be a real problem.

Ed Hare, W1RFI wrote:
"I am not one of them, but I do not believe that strict rules and regulations are always the answer, either."

The only deviation from strict rules and regulations must be granted by jurisprudence in the courts.

FCC should not and can not enforce one word that isn`t clearly written in the rules. If questions arise, the judicial system, including the administrative law system, should resolve them.

You can`t have it both ways. You have strict rules and anything not prohibited by the rules goes, or you have madness.

Best regards, Richard Harrison, KB5WZI

I don't think there is a website that is the 'end all' of things for antennas, but the easiest antenna I have ever built (and that WORKED as it said it would) was a copper J-Pole for 2M. It is built from standard copper tubing you get at the hardware store, and I think mine cost about $6 US to build. Just search on the net or ARRL website for 2M J Pole and that should get you started, Mine was built using the directions in the ARRL 1996 Handbook, but all of the ARRL handbooks should have them in there...

Bill,

I get this kind of threat all the time on this NG. I must tell you that at least two people got in trouble with their management because of such issues.

Imagine---

SAYING:"Yea boss; I know we save the most money and get the best performance with the (patented) fractal antenna--but I just don't LIKE the guy!"

BOSS: " What did he say that you didn't like?"

YOU:" Well, he said the other guy's results were wrong."

BOSS:" Hmmm...according to your hardcopy here, this guy Cohen was saying that the other guy was wrong because he had already built ones like it. And he also asked the other guy to send the file so he could give him some feedback. Sounds like a good way to get closure.'"

YOU: "But I just don't LIKE him. he's such an 'arrogant ass'.

BOSS:" Last month you said that about Bill Gates-- but this company isn't gonna throw away its PC's. Get back to work. besides, the other guy complaining is a competitor and slung enough libel as it was."

This is probably one of the most destructive uses of the internet--not to express OPINION<--but to make tangible and global efforts to destroy a high tech firm. Fortunately, those days are numbered: with this type of manipulation being shut down everyday, its only a matter of time before such libelous activity explicitly has laws written against it.

I've been here 5 years. I am patient. And right.

Thread:

Not with the new fractal light bulbs recently developed by Fractal Filament Bulbs, Inc.

FFBI is a new startup firm provided with seed venture funding by GE Capital. FFBI has developed a new light bulb with the tungston filament bent into self similar (aka fractal) shapes.

This new bulb with the fractal filament is very much more efficient, lower losses, higher and more spectrally pure light output, and much smaller size because the fractal filament is bent into a much smaller space, etc...

In fact this fractal filament bulb is so efficient that GE's refrigerator division is considering leaving it on when the door is closed! Talk about innovation!

So what if the fractal filament is a bit more difficult to manufacture and assemble with it's delicate, flimsy, and kinky filamentary structure? That small lack of robustness is more than paid for with increased efficiency, smaller size, and great fame and fortune rained upon it's inventor, Dr. Latcarf, Ph.D.

Dr. Latcarf, graduated from one of the Ivy League schools, I think it was the one in Schenectedy, NY...

Dr. Latcarf has already established a moderated NG to help support his efforts because he doesn't want to become a "victim" of fame and fortune.

The new FFBI bulb is in fact so efficient that the "appliance bulb" versions draw practically indectable currents.

However, sadly, in the past when GE Capital has funded long life light bulb projects, they never seem to have been a big hit in the marketplace.

I only wish that the fractal light bulb inventors had got their funding from more conventional ROI driven pure financial venture capitalists rather than an industrial venture capitalist with a "side agenda".

We'll see if the FFBI fractal filament appliance bulb product is widely marketed after the next Consumer Electronics Show.

Fractal Filament Bulbs, Inc. have contracted for a display booth at that show in Chicago this January.

I for one am looking forward to it.

I am extremely disappointed with some of the ignorance here.

If you have two values: 27.5 V/m versus 3 V/m we see that the ratio of the two is

27.5 v/m / 3 v/m

This is very close to a value of 10 and it is DIMENSIONLESS.

Now dB is a logarithmic scale. IT IS COMMONLY represented as POWER ratios--BUT NOT ALWAYS!

Thus the ratio of voltages is a 10dB difference (approximate),

IF ONE EXPLICITLY IS REFERRING TO POWER then the voltages square and there is approximately a 20 dB difference in POWER.

Hope this helps. I don't want to see some youngster slinging around the idea that 20 dB corresponds to a ratio of 10.

Never forget that...

The radio spectrum belongs to "we the people".

It is only "by our leave" that we permit regulators and others (ARRL) make suggestions.

At any time "we the people" might just decide (Say by a "proposition" in an upcoming election maybe. Heh, heh, anyone buy this?) to usurp the power given by us to the regulators to oversee "our spectrum".

Thomas Rauch, W8JI is in the process of being sued by me for libel and other illegal infractions.

Since January, 2000, I have asked him to stop harassing and abusing me and he has only stepped up his activities. In that time I have never responded to his puublic or private comments in any way.

Last week he threatened to stalk me at a public talk, and continues to do so with an open house next week.

Mr. Rauch lives in Georgia and thus slows down the civil process against him, as he is out of state.

Mr. Rauch also makes libelous statements in reference to Fractal Antenna Systems, Inc. It needs to be known that Mr. Rauch works as an active consultant for MFJ Enterprises, which is a major supplier of antennas9Telex/HyGain). Both Fractal Antenna Systems, Inc and MFJ Enterprises now compete for certain market niches in the antenna arena.

I urge you to consider the nature and motivation of the destructive and abusive comments from W8JI. They are not motivated by accuracy or information.

Nathan Cohen, Ph.D.

How would you know the switch behaves the same when pressed by the door? What if it doesn't work when pressed at the angle and distance the door presses it? How do you know the current change is due to the bulb going off, and not something else?

I'm afraid without actually going inside the refigerator and watching, or installing sensors to measure the actual changes, you really can't be absolutely sure the light goes off.

The most reliable test is always the most direct test, assuming you have instruments that detect the changes. Instead of connecting your senses to the light through instruments and wires that can fail, the best thing to do is go inside the refrigerator and have someone shut the door. Then, if your eyes happen to fail at the moment the door was closed, you could feel the bulb to see if it was cooling. You could stick your ear on the bulb, and listen for the filament vibrating from 60Hz AC. You could unscrew the bulb and put your tounge in the socket and see if it tastes like there is no voltage. You could smell the bulb, and see if it smells like it might be hot.

Then you would have to leave the refrigerator, and repeat the test seveal times with different testors to be sure no one was cheating.

When that was all done, you ship the data to Nathen Cohen, PhD and let him use incoherent averaging to factor out all the noise in the data.

Without all these steps, there is no way you can be sure the light goes off.

Ed:

Thanks for that analysis.

From empirical evidence, I too believe that the WSB em field was harmless.

I sat in it [My office was at the 41st floor level, about 5 blocks from the antenna, which was even higher.] daily for four years and I'm still fertile, heh, heh.

Regards,

Peter

Source record: 181266

Greetings--

I will be holding an open house from 10-1 on Saturday, Sept 16,2000 with my fractal-equipped station. Both the 10M FQY and the 20M K2 Fractal Flyer (see ham page of

http://www.fractenna.com)

will be up for operating from N1IR. I will also have my station logs available for viewing the many successful 10M QSO runs I have experienced wit the FQY.

Please let me know by 12 Sept if you wish to attend; attendance will be limited. Also, PLEASE LET ME KNOW WHAT TIME YOU WILL BE PRESENT as unuathorized cars will be towed due to restricted street parking. And please bring your license if you wish to operate.

I regret that some individuals will not be permitted to attend, due to their previous on-line behavior.

I am located in Belmont, MA, next to the new Boston Temple of the Mormons. I am 5 minutes from 95 (128) and adjacent to Rt 2. I will forward directions to those attending by 15 Sept.

Hope to see you then.

1603. Re: Near Field / Far Field

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-09 12:43:54 UTC
From: w1rfi@aol.com
Message-ID: <20000909084354.20785.00000372@ng-cf1.aol.com>
Source record: 181121

>What causes the near field / far filed effect when measuring field strength
>in a miniture AM transmitter?

Hello, Scott,

A complex subject. :-) There are actually two near-field phenomena; it only adds to my confusion that they are both called "near field."

The first is the "reactive" near field. In this region, very close to the antenna, energy is being put into the field, then almost immediately taken back -- well, most of it is taken back. This field exhibits the same characteristics as reactance in a circuit. The electric and magnetic fields can be very high in the reactive region, varying as 1/d^2 or higher.

Some of this energy, however, is not taken back, it becomes radiated. Once the energy is radiated, that portion the field *could* vary as 1/D (remember, we are talking individual electric or magnetic fields; the em field, comprised of the electric and magnetic fields traveling together vary as 1/D^2). (Actually, the radiated field from any infintesimally small part of the antenna does vary as 1/D, but the total field at any point is influenced by all of the infintesimally small parts of the antenna.)

From a point source, this radiating portion of the fields being created near the antenna would vary as 1/D, but at any one point, one is seeing the energy being radiated by each portion of the antenna. At a point very far from the antenna (the far field), all parts of the antenna are pretty much equidistant from each part of the antenna, so they all influence the field at that point equally, in proportion to the voltages and currents on each part of the antenna.

However, when one is very close to the antenna, one is NOT close to the antenna, one is close to *part* of the antenna, and farther away from other parts. So the field at that point is influenced more by some parts of the antenna than others. The net effect is that the electric (E) field and the magnetic (H) field are not necessarily at the far field relationship of 377 ohms; the E and H fields are not necessarily at right angles from each other and they do not necessarily vary with 1/D, but could even vary inversely.

For example, if one starts measuring the fields very near a high-impedance portion of the antenna, one would find a very high E field and a very low H field. As one moved away from the antenna, the measured E field would probably decrease faster than 1/D and the H field would probably *increase*. This is because as one moves away from being very close to the original point, the proportional effect of the different parts of the antenna that are radiating fields into the EM wave being created is different. As one approaches the far field, each antennna portion becomes closer and closer to

have the same influence as the other parts.

Where does the near-field and far-field "boundary" exist? There is no boundary. As one gets farther away from the antenna, one sees a relationship between the fields that is closer and closer to what it would be very far from the antenna. One is in the far field when the deviation from "ideal" is small enough for the purpose.

The general rule of thumb for the near-field/far-field boundary is:

FF = 2 * D^2/lambda

This would be a pretty good far-field distance for making field strength measurements or for measuring the far-field pattern of a dipole (errors would probably be less than 1 dB). But it probably would not be enough in the far field to measure the deep null the pattern of two phased verticals; one would probably have to be much farther away than that to make measurements accurate enough to be -20 dB from the main lobe.

There are certainly some good mathematics to describe the above "intuitive" explanation, but I do not know that they are. If any of the real experts here care to post some references, or a more technical explanation, I would welcome it. If any of the better writers care to post a more concise explanation, I would welcome that, too. :-)

One of the slickest ways to "test" one's connection to a newsgroup is to select a post, and post a reply. One can usually think of something to say, even if it is. "That is the most well written post I have ever seen; thanks!" It accomplishes the test and gets you out of the "silent majority" mode and into the action. :-)

If you are testing because you haven't been here before, welcome to the NG!

For a great performing 10m antenna, go to www.copper.com, and look at the
Wilson 1000 series. You can probably find them elsewhere, but copper will
probably have the best price. I run one on the top of my Blazer. SWR
bandwidth at 1.5 to 1 or less is almost 1 full MHz. With a tuner, I also
get good performance on 12m.

> If I read your message correctly , you described it perfectly with the
> coils, It probably isn't gonna work.... correct?

While you're there, look at some of the other antennas. You'll find what
you have there now also.

1613. $1000 FRACTAL ANTENNA CHALLENGE

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-09 13:15:49 UTC
From: fractenna@aol.com
Message-ID: <20000909091549.15785.00000431@ng-cd1.aol.com>
Source record: 181129

Still nothing close:-) Happy to look over your file before you 'officially enter'.

Good luck!

73,
Chip N1IR

In order to encourage hams to understand the importance, advantages , and excitement of fractal-element antenna (FEA) technology, I am personally sponsoring a contest.

The objective of the contest is to produce any sort of antenna which has a performance advantage over the MI2 fractal loop element:

(see, for example, the ham page of:

http://www.fractenna.com)

Here's the rules:

OBJECTIVE: produce and model an antenna design with a superior figure of merit (FOM) compared to the MI2 design at it's lowest resonance., from a single contiguous piece of wire. Any form of load must be expressed as a wire form and not discrete components. Size must fit in a form factor of about 1/8 by 1/8 wave. Frequency 14.15 MHz.

FORMAT: All designs must be submitted as .ez model files. See http://www.eznec.com for EZNEC info]

FOM: (10 X(dBMax) + 5X (BW in percent relative to 50 ohms) + efficiency in percent)

[Note: I kept it simple on purpose so that no one will think this is an a posteriori bias] The dBMax must be a field strength, not a gain. That means it includes non-radiative losses]

DEADLINE: 30 September 2000.

SUBMISSIONS: An e-mail stating the FOM value to chipn1ir@aol.com. Only the best will be requested to submit the .ez file. DO NOT submit the .ez file unless requested.

RESULTS: POSTED ON this NG by 1 Nov 2000. In the event of no-winners, the closest value and design will be announced on this NG at that time.

Best of luck to all--

And learn about this exciting and useful technology!

1. Put a lamp-socket-to-prong adapter inside the frige. Run an extension cord to the outside to the indicator of choice.

2. Drill a peephole in a wall of the frige. Avoid the refrigerant lines.

3. Replace the door with a transparent one.

4. Have the local replacement window scammer put a vinyl or glass-block window in one of the walls.

5. See if mushrooms grow better inside.

Chip, N1IR wrote:
"Thus the ratio of voltages (27.5 v/m / 3 v/m) is a 10 dB difference approximately."

That is a mistaken idea.
db = 10 log (power ratio)
and
db = 20 log (voltage ratio)
are really identical expressions.

If the voltage ratio is 10, (2) is the exponent needed to raise the base10 to the value of 100 which is the power ratio represented by a voltage ratio of 10. Ten times the voltage produces ten times the current and power is voltage times current, so the power ratio is 100.
db = 20 log(10) = 20 (1) = 20
or
db = 10 log(100) = 10 (2) = 20

The answer is the same whether the voltage ratio or the power ratio is used. This is as it must be because they are expressions of the same actual value.

Best regards, Richard Harrison, KB5WZI

QST--

You are invited to join one or all of the following lists on e-groups(formerly onelist). All these reflectors are e-mail based, friendly, objective, and moderated ,so that no spam, porn, off-topic, or personal-offensive posts are sent out. You will receive no off-list e-mails by subscribing: again; no spam.

These lists (with average recent subscriber sizes) are:

ANTENNAS@EGROUPS.COM 176 members
CROSSFIELDANTENNA@EGROUPS.COM 70 members
FRACTALANTENNA@EGROUPS.COM 255 members

Please review the descriptions at:

http://www.egroups.com

Please note the CFA list specifically deals with this antenna in an objectively critical fashion and no posts will be allowed that make grandiose claims without supporting data presented. To date, no data has been presented which requires the extraordinary claims made by some pundits: there is no evidence for better performance than any other small vertical antenna (and that performance is poor).

Fractal antenna posts should go the the fractal antenna reflector; not the antennas reflector.

To subscribe to any list, either go through the process at egroups, or to skip the process (and some say 'annoying questions') just do:

---------- -subscribe@egroups.com

where the ---------- is the name of a given list (such as 'fractalantenna')

If you have a specific question on this post, please e-mail me off-NG at chipn1ir@aol.com.

73,
Chip N1IR

New definition of OPEN HOUSE? Not to worry.

We will come by trains, planes, automobiles and with court order allowing anybody to enter that open house. Once it was advertised as open house it is open house. We will gladly park far away, but we have to see and touch the miraculous antennas and all those geniuses and meet their families. TV and Voice of America are also coming, it is going to be live broadcast to the world to give this deserved genius and his freaksonalities proper exposure after so many years of suffering on this bunch of PDH NG.

Gentlemen, start your engines!

Ed Hare, W1RFI wrote:
So in the far field, the electric and magnetic fields vary by 1/D while the power density varies as 1/D^2.

Yes, if you have 0.2 v/m at a mile and 106 microwatts per square meter, you have an unattenuated field producing 0.1 v/m at two miles and 26.5 microwatts per square meter at two miles. The inverse square law applies to the power in the wave (equally divided between the E & H fields) while the 1/D rule applies to the volts / meter.

When estimating field strengths I find it helpful to remember that the dilution caused by spatial expansion of the wave is 22 db attenuation in the first wavelength, then 6 db additional every time the distance doubles. As an example, the total attenuation is 28 db after the wave travels 2 wavelengths, 34 db after 4 wavelengths, etc.

At last--the first sensible suggestion I've seen to date!!

Realistically, a .357 would be the fastest way to aquire a suitable peep-hole. Don't try to patent this important "breakthrough" method, though. If you try, you'ill likely be sued by Jimmy Buffet (and his wealthy Uncle) for infringmement on prior art. Seems Jimmy already holds a copyright in the lyrics of a song dealing with the pressures of cabin fever and a need to escape to someplace warm. Damned rich people!

Besides, it's illegal in most states to shoot a giraffe.

Please read my previous posts Richard. What I said, in summary ,is that dB is a logarithmic scale that usually refers to power. However, we are not talking about powers here.

We are talking about voltage densities.

Thus

27.5 V/M / 3 V/M

is a dimensionless ratio corresponding to about 10 dB, where the dB refers to the units so used. Formerly, it's about

10 dBV/m

It is impossible to get power from these measurements. They are voltage densities, which, by dimensional analysis can never, ever, be translated to power.

Thus if you formally wish to restrict the dB method to POWERS, this will never apply.

Of course, one may take the voltage densities and calculate them as POWER DENSITIES (NOT power). In this case it is perfectly legitimate to square the values so stated to get a dB difference in POWER DENSITIES, which would thus be about 20 dB when expressed in the proper units.

With Best Wishes,
Chip N1IR

Hey:

What is wrong with the good ole USENET NG's. These venerable fora have been working efficiently since the beginnings of the Internet.

Why do we need new era NG's? Because some can't stand the "heat". As our beloved Harry Truman said, "if you can't stand the heat, get out of the kitchen!"

Opportunists, carpetbaggers, charlatans and profiteers seem to be setting up new lists and NG style operations and are trying to lure participants away from the long standing open and relatively commercial free fora provided by the USENET news groups.

I believe that the intents of these "shanghai" artists is to only further the business interests of those who wish to commercialize an inexpensive non-profit motivated open forum for discourse...

Comments, thoughts?

Steve,
unfortunately you are dealing with joker. You can get better arguments from a brick wall or a piece of bamboo then from Freak.

Way back (when I didn't know the Freak) I offered $1000 prize and challenged him to bring his Fructal antenna to one of VHF antenna measuring contests and show that it will beat my antenna of similar envelope. Loooong, dead silence. Must have been affraid of impartial measurement of the real thing.

Then when newspaper was interested in writing up story about his magical twisted wires, and found out that Freak did not take up the challenge, Freak did his freaky thing. He "accepted" the challenge, by under his "rules". By then I realized who am I dealing with and since then I enjoy occasional comedy and entertainment that Freak is providing.

You could go through the archives, read the "history" and get the full story, but I doubt it is worth it. If you engage with him in any argument or discussion, you will eventually end up being threatened to be sued. We are trying to ingore him, maybe he will go away, but new people join here and get sucked to his trolling and it takes while to realize what are they dealing with.

The rest here are sane people, so stick around, just take the Freak for what he is, have fun. You can never win with him, he is perfect, never makes mistakes, always right even if wrong. What else can be said?

>>I think the power to make suggestions is given to Dave by the Constitution.<

>"constitution"?

Actually, no, I meant the US Constitution. The right of people and organzations to make suggestions is covered under the provisions for free speech. Those same provisions also give people the right to decide whether to ask the government to make those suggestions into law, in which case everyone has to follow them, or leave them as suggestions, in which case people are free to follow them if they think they ara good idea.

On what basis would you offer that Dave should not be permitted to make suggestions to the amateur community?

Chip:

Well my hearing problems (tinnitus) certainly pre-date my WSB AM antenna field immersion and so that's not correlated.

Heh, heh, Fertility, well.... I believe you may have hit on something else though... you could be right.

My poor deceased father once told me that "hearing" is the second thing that goes... and so...

If I do have fertility problems now, it also might have predated the WSB field immersion.

I agree that I do not have "definitive" proof of my current fertility since, usually only the mother knows for sure who the father is...

and so...

I am prepared to stand corrected on the fertility issue.

Of course, as an engineer, I will only accept correction of my fertility status upon submission of incontrovertible DNA evidence.

Chip, Tom and I are looking forward to the open house.

I hope those "latter day saints" don't ruin the propagation.

Yuri--

You'll likely see yourself on Boston TV during your grand entrace. Confidential media sources predict several disgruntled Ledgewood Place residents have planned events for that day in an effort to disrupt traffic flow to the new Morman Temple's open house which is schelduled concurrently. Should be lots of congestion, confusion, police, media, choppers overhead, and a huge backup on the inbound side of Rt 2 as vehicles attempt to enter and depart the narrow and paritally-clogged suburban street! Since 2 Ledgewood is at the very entrance of the streed, it is especially stategic. Show your courtesy by parking with all four wheels on the pavement so as to preserve the conditions of lawns boardering the roadway. Also, leave your car in a high-ratio gear to ensure extensive transmission damage, should it be illegally towed by the City of Belmont (great way to get a new set of wheels). Cross-country truckers and "Hum-V's" owners will be given special priority on the guest list.

If you've got a b-i-g amp, bring that along, too. Might be a great opportunity to test the Temple's PA system for RFI!

Rick K1BQT

Disclaimer: I have no idea at all if any of this is true, but if someone stuck that monster temple in my back yard, I'd sure be PO'd!!

Perhaps a quote from "Reference Data For Radio Engineers", Howard Sams -
1975 will be helpful. Under fair use:

Section 3-15 Titled "Decibels and power, voltage, and current ratios"

"The decibel, abbreviated dB, is a unit used to express the ratio
between two amounts of power, P1 and P2, existing at two points. By
definition number of dB=10 * log10(P1 / P2). It is also used to express
voltage and current ratios: number of dB=20 * log10(V1 / V2)=20 *
log10(I1 / I2). Strictly, it can be used to express voltage and current
ratios only when the voltages or currents in question are measured at
places having identical impedances."

Tom:

Or rather an example of fractured dB usage.

It seems that Chip is getting reckless and sloppy with definitions again.
Just don't fly on any airplanes designed by Chip!

BTW... the operative unit is not the dB, rather it is the Bell abbreviated
B.

The Bell is named after Alexander Graham Bell, a native of Scotland,
inventor of the telephone, one time Canadian, resident of Brantford,
Ontario, of Baddeck, Nova Scotia, and of Boston, MA.

As Chip stated, one tenth of a Bell, known as the deciBell widely
abbreviated as the dB is indeed a logarithmic measure of numerical ratios of
like quantities which perforce are necessarily dimensionless units .

The conventional and usual electrical Engineering usage of dB is in the
measurement of ratios of powers. [i.e. dB is defined in all textbooks,
reference books, handbooks, and technical dictionaries to be 10 times the
logarthim to the base 10 of a ratio of two powers. --- End of story, Chip
is WRONG!]

Chip's assertion that it is defined as a ratio of other quantities is not
the normal or usual usage of dB's.

In many parts of the world outside of America [Reg won't like that usage,
heh, heh.] the Neper or Np is the operative unit.

The Neper or Np is based upon Naperian or "natural" logarithms.

Natural logarithms, as every scientist knows, and engineers don't care, is
defined by a certain definite integral.

And so... in Germany, France, Japan and other advanced countries, one will
find Np in wide use rather than base 10 logarithms as is the Bell [B] and
dB. There is no common fractional nomenclature for fractions of a Neper
such as deciNp, etc...

It seems in my long experience of hiring and managing both Engineers and
scientists, that scientists just don't get dB's.

I have come to the conclusion that misuse of dB's by scientists is simply
because dB is an Engineering unit and scientists feel uncomfortable with
Engineering units.
Scientists seem to feel that the important part is that the "dimensionless
argument" of the dB function is the upper limit on a definite integral and

that multiplying it by a factor of either 10 or 20 is of no consequence.

Details, details, don't bother me with details...

As you know Engineering is a Profession, and science is merely a field of study.

Hence scientists are often "sloppy" in their practice and use of scientific measurements and constructions.

In retort to their complaints, I would ask, "Mr. Scientist, would you rather fly in an airplane, or cross a bridge, designed by an Engineer or by a scientist?"

Accuracy and precision are legal requirments of a Profession like Engineering, but not of scientists.

Hope this helps others in understanding correct dB usage.

Chip, N1IR wrote:
"It is impossible to get power from these measurements."

It is possible, I believe, to infer power from these measurements. If not, I don`t know what i`m missing.

A radiated power expands producing a density which declines in watts per square meter in the wavefront as it expands throughout space. The same total power is in the wavefront at any distance from the sender minus other losses which may be encountered enroute.

The volts per meter are representative of the power in a square meter of the wavefront.

Best regards, Richard Harrison, KB5WZI

No fair using a real reference :-)

As a side note, it is implied from the definition that the values being
compared are in the same units and you are therefor taking the log of
a dimenionless ratio. If the ratio weren't dimensionless, you wouldn't
be getting decibels.

I would think a scientwist would know such basics, or is this just a really stupid troll.

Yuri:

How thoughtless of you.

A completely one-sided view.

You explained Fractenna to Steve, but you didn't advise Steve to stop his attempts to victimize Fractenna.

It's tough trying to champion new ideas without having folks show up demonstrating superior comparables.

And clearly we can all see that Steve was attempting to terrorize and oppress the poor victims at Fractenna with his superior antenna design.

Why not tell Steve to cut Fractenna some slack, tell him to stop challenging Fractenna, tell him that new ideas deserve a honeymoon or incubation before being attacked or compared to other ideas.

Yuri, your support for Steve could end up costing Fractenna $1000.00 of hard earned American taxpayer dollars!

Remember that we have all contributed to that fractal antenna research through the thoughtful distribution of our tax dollars by one of our Federal agencies, at least we could cut them enough slack to let them keep the $1000.00.

On the other hand, maybe you are a proponent of the theory of "survival of the fittest", and like the Roman Mob you just like to see the best antenna win.

Thoughts, comments,

Then you would, by definition, state that it its not relevant to compare two measurements in units of V/m --with a dB scale. Such units can never, ever, be represented as a 'power'.

The fallacy is obvious.

May I suggest that if you perceive an error in my statements that you annotate each comment and correct it accordingly.

I state categorically, that my statements on this topic are accurate.

With Best Wishes,

Chip N1IR

Chip, N1IR wrote:
"Thus the ratio of voltages (27.5 v/m / 3 v/m) is a 10 dB difference approximately."

Maybe I need to be more succinct. This is approximately a 20 db difference because it is a voltage ratio, not a power ratio, as expressed.

The number of db`s derived from a particular ratio are, for a voltage ratio, double the number of db`s the same ratio would produce were it a power ratio.

Never mind the theory, just follow the definitions.

Best regards, Richard Harrison, KB5WZI

Chip:

Uh... police! Stalkers? What!!!

Wow, you never told us that.

Open house with police... say, you do lead an exciting life up there in Belmont, MA!

If you need police protection and expect stalkers, why on earth would you hold a publicly announced open house? You must be crazy!

You've got me worried now... I'll have to reconsider.

You seem to be enticing me to attend a potentially dangerous event. I hope you have arranged for liability insurance for that open house.

Will the police be armed? Is gunfire likely to break out? If it does, can I count on the local police for protection?

My dear wife is reading here over my shoulder and she is telling me in no uncertain terms that she absolutely forbids me to attend your fractal antenna open house event, she says if it is so dangerous that you need police protection, I am to stay away.

Is there anything that you can tell the NG to asuage my wife's feelings of dread and doom about your fractal antenna open house?

Tom, if you are reading the mail, I'm calling the trip off, I have to be at the DSLcon conference in downtown Boston on the following Monday but, unless I get absolute assurances of my safety at the Cohen "Ponderossa", I won't be attending the Saturday open house.

Maybe I can get Chip to invite us to a "private showing" rather than attending a "risky" open house.

Chip, what say, can Tom and I come for a private showing, say on Sunday?

Then we have a subjective and incorrect assertion as opposed to something accurate and demonstrated--at least from you.

I do care for the truth. If I am not stating the truth then you have an obligation to follow through, given this is a public and global forum.

Tell you what: IF I am wrong, then I will resign my teaching position effective immediately, as according to you, I am incapable of conveying accurate and fundamental info.

The truth is ALWAYS worth serious stakes.

Hope you objective follow through.

With best Wishes,
Chip N1IR

That is still correct Richard. Please R E A D my posts:-)

You can never get units of WATTS from the dimensions of V/M without invoking an additional, dimensioned quantity--which is not part of this measurement.

Chippy,

Only by accepting our mistakes and correcting them do we advance.

If you ever admitted you were wrong, or even quietly accepted the fact
you were wrong and moved on, my opinion of you would increase by 100
dB (that is in either voltage or current ratio...or power).

As it is, you could have 1/4 the IQ you have and advance 50 times
faster if you didn't have your head so firmly stuck up your ass you
can't see daylight in the noontime sun!

How on earth does an absolute moron like you get a PhD? By irritating
people so much they give you a degree just to get you the hell away
from them?

Hi Ed-

Having put in some time defending Dave's right to free speech, I have no problem with him exercising it.

What I do have a problem with is when an individual's "suggestion" is driven by special interests and takes on the form of "mock rulemaking" in an approval process by a board possessing no regulartory authority whatsoever. This may confuse some amateurs. Fact is, bandplans don't carry the weight of the paper their written on.

FCC Rules, on the otherhand, do. If there was a CW/Digital segment designated on the low end of 160 by FCC Ruling, for example, swarms of contest whackos on SSB wouldn't be driving everyone else off that portion of the band at their whim.

Only one captain gets to drive the ship. Technically, shouldn't anyone who demands you to move because of a bandplan be turned into the FCC for willful interference? Legally, that's what it is--and the League encourages it!

Hi Ed,

Maybe someday Rick will learn to speak his mind!

I think the problem is many people view the ARRL as a politcal organization designed to serve itself, rather than serving the amateur community.

Sort of like a minature Congress or Senate, with a lifetime president, making decisions based on sustaining employment rather than whats good for amateur radio in the long term.

I can understand that view, looking at all the decisions I've seen in policy. You don't need to answer, I'm just trying to convey what I think Rick was saying in different words.

>be represented as a 'power'.

That is not correct, Chip. The units of V/distance and A/distance in representing fields are related to (power/(distance^2) by virtue of the impedance of free space (377 ohms). So an electric field of 1V/m has an implicit relationship to power because by defintion, a field is occuring in a free space impedance of 377 ohms.

To convert V/m to power density, use (V^2/377)/m^2. Because the impedance is identical in comparing 3 V/m and 27V/m as it relates to radiated fields from an antenna, it is perfectly valid to use the formula 20*log(V1/V2) to obtain the difference between the two units in dB.

The ONLY definitions I have ever seen relating to the bel, the basic unit behind the decibel, state that it the log10 of the ratio of two powers. I have never seen it applied to anything else in any text book ever. Can you supply any reference that indicats that the bel is a ratio of pure numbers? the log10 function is very much a ratio of pure numbers, although log((X/n)/(Y/n)) is a perfectly valid operation for which the n's cancel out. But by defining the bel as a ratio of two powers, then one can use log(P1/P2) for power and one can ONLY use log(V1/V2) if V1 and V2 are both in the same impedance. In the case of radiated fields, they are.

I do not believe the bel could be applied to pure numbers, because if it were, then 10*log ((1/1)/(1/1)) would be = 20*log((1/1)/(1/1)) if in the first case, we were discussing pure numbers and in the second case, we were discussing those same numbers representing voltages measured in a circuit of 1 ohm.

With the definition that bel = log(P1/P2) and bel = 2log(E1/E2) then normalizing R to 1 ohm, then bel = log(E1^2/E2^2) - 2log(E1/E2).

It is quite relevent to compare ANY two measurements (in the same units) and
give the ratio as dB. It is also common engineering practice.

Expressing ratio in terms of dB does NOT imply you are comparing power.

One does need to take care to apply the correct multiplier, i.e. 20, if the
base unit is Volts, as in V/m.

No one but the estimated scientwist of the group is saying that the unit
V/m is a unit of power.

Since the Chip arguement is so totally clueless, I have come to the
conclusion he is argueing simply for the sake of attention again.

Chip reminds me a lot of a guy I knew in the Army who would make the most
outrageous, obviously incorrect statements just to see who would rise to
the bait. And, suckers that we are, we responded to Chip's silly post.

For a field of E/m, the plane-wave equivalent power density is equal to:

pd(W/m^2) = (E^2/377)/m^2

Dear reader,
Checkout our classics factory show on www.dancenet.fm every saturday 17.00 CET. If you can't listen at that time no problem, the show will repeated on the sunday after

Saturday the 16th of spetember we have a special item around Ben Liebrand, the remix master himself. Including an inteview and one of his famous minimixes, and his personal top 5.

Tune in to www.dancenet.fm the number 1 cyber dance station.

Chip N1IR wrote:
"You can never get units of WATTS from the dimensions of V/M without invoking an additional dimensioned quantity."

We trust that in a resistance of ANY type the current will be proportional to the voltage, Ohms law will apply, and the power is the voltage squared divided by the resistance.

We have a 377 ohm value for free space. (Maybe I should refer to a book, but I`m not designing a jet aircraft so I don`t absolutely have to be right on this.)

Best regards, Richard Harrison, KB5WZI

The decibel is defined as a power ratio in the references I have handy. Interestingly, the definition of decibel is not even mentioned in all my antenna reference works - I guess it's considered a high school physics thing (that's where I learned this.)

So, for the benefit of any wandering innocents who have blundered into this silly discussion and are being confused by some of the arguments, the book "Reference Data for Engineers: Radio, Electronics, Computer, and Communications", Edward C. Jordan, Editor in Chief, 7th edition, Sams, 1991, defines it thusly:

"The decibel, symbol dB, is a dimensionless unit for representing the ratio of two values of power. The number, n, of decibels is 10 times the logarithm to the base 10 of the power ratio:
n(dB) = 10 log10 (P2/P1)
In the electral case of voltage, V, Current, I, and impedance, Z (when Z is a pure resistance):
P2/P1 = (V2/V1)^2 (Z1/Z2) = I2/I1)^2 (Z2/Z1)
Thus,
nV(dB) = 20log10(V2/V1) + 10log10(Z1/Z2) and
nI(dB) = 20log10(I2/I1) + 10log10(Z1/Z2)
Only in the special case of matched impedances (Z2=Z1) does
n=n(z-matched) = 20log10(V2/V1) = 20log10(I2/I1)."

My unabridged dictionary also says that the decibel is a way of expressing power ratios.

Note also that a ratio of any like quantities will always be unitless.

Note also that starting with defining the decibel as a power ratio leads one to immediately see that by Ohm's Law, the value of power can have E^/Z or I^2/Z substituted for P in the ratio. And if it is understood that a situation of equal impedance is being considered, that it is quite correct to use 20log(E2/E1) to calculate the decibel power ratio. Frankly, I don't see how a 10log(E2/E1) situation could EVER happen. Maybe for deciCohens but not for deciBels.

Yes. In an earlier posting I wrote:"---producing 0.1 v/m at two miles and 26.5 microwatts---

01 / 377 = 26.5 microwatts. That 377 was the resistance (non-dissipative) that I was using in my example.

>From: 2w8ji@contesting.com (Tom W8JI)

>Ten dB isn't much if you only plan on working stations that are
>strong, but even 1 dB can make or break a signal under less than good
>conditions.

I agree. I can think of a number of cases where that applies. In the QRP world, I have more than once spent some trying to dig a fellow QRPer out of the noise. One dB can make a difference between just being able to tell someone is there, but not being able to extract the call signs or just being able to tell someone is there and completing a QSO. Ditto on some of the CW work I have done on VHF.

Big gun contesters know that every dB is important, both to just edge out the other guy in a pileup if you can, but in keeping the rate up in getting answers to CQs. There are a number of people who only answer the louder stations, and every dB can help.

>I think part of the misconception that 5 or 10 dB is not important
>comes from looking at S meters, and assuming they are 6 dB per S unit
>across the scale.

In QRP work, contests, pileup busting, etc., 5-10 dB can make all the difference in the world, I would guess about 20% of the time. In a single QSO, the difference between 20 dB over 9 and 30 dB over 9 will not usually make a shred of difference.

>It takes very little work to move a vertical from a 5 or 10%
>efficiency radiator, which it will be with a single radial laid on the
>ground or just above ground, to one that is 50% or higher efficiency.

Now, are you talking voltage efficiency or power efficiency? :-)

I guess I could be upset that people don't read, but I will attempt to be amused.

I repeat: a measurement in V/m can NEVER EVER be converted into a power.

Most freshman (science, engineering) freshman in college learn this in their chemistry classes, where profs are especially unforgiving about conversion of units and dimensional analysis. Less so in intro physics. Usually reasonably 'hand waving' in engineering:-)

If stating the truth puts me in the most 'outrageous' category, then please
keep in at the top of your list!

It's really amazing that Ed and others INSIST that you can get power from a
measurement of V/m.

I am a bit taken aback when Ed says how wrong I am--that you CAN get POWER--and
then in the next sentence calls it a POWER DENSITY.

The two are hardly the same. You cannot get the power from the power density measurement. More info is needed. Just use dimensional analysis to balance it out and figure what is 'missing'--even though the answer is obvious.

Thanks for FINALLY agreeing Ed!

Power density is NOT power. Power cannot be extracted directly from the v/m measurement. More info is needed.

Hello Klein--

Please follow my posts.

dB is not exclusively used to describe powers (which I already said).

But let's take, for the moment, the original post from W1RFI:

>The levels in various immunity standards are approximately 3 V/m. The levels
>in the RF exposure standards are >= 27.5 V/m. It is very difficult to
>correlate RFI and RFX issues with 20 dB of difference between the two.
>
>73,
>Ed Hare, W1RFI

Since neither measurement gives POWER, your definition would require that dB is not an acceptable means of description.

In fact, dB is used for purposes other than describing power. In this case, there is the almost 10dB difference in v/m. From this ONE CAN GET THE POWER DENSITY which is about 20dB..you figure out the units:-) It ain't watts!

But I said all this already:-)

Dimensional analysis lives:-)!

I will say it again. You CANNOT convert a measurement in V/m into a POWER.
You CAN convert into a POWER DENSITY.

More info is needed for POWER.

If what everyone insists is that it's ok to be sloppy between a 'power density'
and a 'power' ...uh uh. that's a no no. You will never ever convince me for the
simple reason that it is not tenable.

Page 17.1 of the 1995-2000 ARRL Handbook (I wrote it) has a discussion of this subject. It goes like this.

Consider two resistors R1 and R2 with voltages V1 and V2. The power ratio is:

Ratio = V2^2/R2 divided by V1^2/R1. The dB *difference* is 10 log(Ratio).

If (and only if) R1 = R2 then the dB difference is 20 log(V2/V1). This applies also in space (377 ohms) for the far field. This is easily derived from the algebra of logarithms.

Both of these satisfy the formal definition of dB.

But there is another usage that is strictly speaking not rigorous, but is widely accepted in practice. It is "inherited" from the vacuum tube days, when we used a VTVM or a high impedance spectrum analyzer probe to trouble shoot by comparing the voltage readings of a unit under test with the pre-recorded readings of a unit that was known to be good. We do this today in solid state gear. We say that the readings are so-and-so dBs different, 20 log(V2/V1), based on *voltage only* readings. In fact most voltage-measuring instruments such as VTVMs and spectrum analyzers(with hi-Z probes) have scales marked in dBs. The values of the circuit resistances are ignored and may even be unknown. This is *very* common practice even when R2 and R1 are not precisely (or even approximately) known. This method is not foolproof, but very often it works OK.

I personally have no philosophical hangup about this as long as I understand what I am doing.

Chip, N1IR wrote:
"I repeat: a measurement in V/m can NEVER EVER be converted into a power."

I repeat: a power can be inferred from a voltage measurement when you know what reistance is producing the voltage drop.

Further, for a db difference, you don`t even need the resistance value. You just need to know that the same resistance value produced both voltage drops being compared, and that these measurements weren`t upset by the instrumentation.

On or about 09 Sep 2000 12:02:29 GMT, fractenna@aol.com (Fractenna),
using the forum rec.radio.amateur.antenna did say:
:BOSS:" Last month you said that about Bill Gates-- but this company isn't gonna
:throw away its PC's. Get back to work. besides, the other guy complaining is a
:competitor and slung enough libel as it was."

Um... Microsoft's operating systems aren't the only OS's that run on
PC hardware... NetBSD, FreeBSD, OpenBSD, Linux (8+ variants), and
Solaris all run on PC hardware. There are, I'm sure, others as well.
This point of yours, like others you make, has only a partial basis in
the facts, and the rest is pulled from whatever universe and/or mental
state your mind resides in most of the time.

:
:This is probably one of the most destructive uses of the internet--not to
:express OPINION<--but to make tangible and global efforts to destroy a high
:tech firm.

Seems to me you are the only one making statements of fact which have
no real basis. Others here seem to be expressing their opinion, and
you go nuts over it, Chip. The animosity seems to stem from the fact
that you have yet to provide concise. nonpartial, comparitive
performance data about any of the fractal antennae you claim to have
built. You refuse to believe that anyone can build a variant of any
non-fractal antenna and get performance out of it that exceeds the
vague outlines you have provided to the newsgroup.

Maybe answering the questions, providing the nonpartial data in the
first place would have avoided all this animosity.

:Fortunately, those days are numbered: with this type of manipulation
:being shut down everyday, its only a matter of time before such libelous
:activity explicitly has laws written against it.
:
:I've been here 5 years. I am patient. And right.

You may be too far to the right.

1688. Re: Bandwidth - 3 el 6 meter

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-09 20:09:30 UTC
From: ehsjr@bellatlantic.net
Message-ID: <39BA993E.CB05D46E@bellatlantic.net>
Source record: 181205

Thanks. SWR bandwidth is the best indicator I have.
I'll discuss that in detail later in this post.
I don't care about gain. With 3 elements and 44" spacing
you can't do much better than whatever gain it produces.
Besides, I can't measure gain, and Id rather have a little
less gain in favor of more bandwidth, in any event.
F/B is irrelevant here. The band is pretty dead most of the
time, and I'll be using this antenna during the dead months.

On the VSWR issue - I'm measuring it with the antenna in
the driveway through 20' of RG 8M. I add and remove a 4'
coax jumper during the measurements, just to be sure I'm
not being deceived due to coax length. When the thing goes
up on the roof I'll re-adjust the gamma. Raising it does
change the SWR.

On to the statement that VSWR is not a very good indicator
of antenna performance. True. And False. For most hams,
it is the BEST measure, simply because we do not have the
means to measure anything else. If a ham had an antenna
test range, measurements other than SWR would be possible
and beneficial. And as to indicator, the best indicator is
listening with the rig. If you hear more with the new antenna
than what you heard before, the antenna is a "good" performer.

For probably better than 99% of hams, F/B and gain are text
book or modelling program numbers and are important at the
design phase of the antenna. Once a design has been chosen,
those numbers are irrelevant. A few of those hams may have
the ability and interest to spend the time tweaking the antenna
for maximum of gain, or F/B, using a field strength meter. The
ARRL handbook and the ARRL antenna book, plus a calculator
gave me some good design info and an expectation of gain and
F/B for this antenna, but I couldn't figure out VSWR bandwidth
with the same kind of expectation of what it should be. So that
was why I asked about it - hoping that those who had experience
with 3 elements on 6 would know roughly what I should expect.

Chip, N1IR wrote:
"You CANNOT convert a measurement in V/m into a power."

Physically this is happening countless times at this very moment.

Put up a wire in the best conditions in an electromagnetic field of so many volts per meter. Then, the voltage induced in the wire can be very nearly the volts per meter of the field.

Half the energy captured will be absorbed by a load matched to the radiation resistance of the wire. The other half of the energy will be reradiated as represented by the radiation resistance.

If we use this particular arrangement to capture different voltages per meter, the powers will conform to all db measurement and relationship requirements as we surely have the same impedance for all measurements.

1690. SGC-230 Pro tuner problem revisited

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-09 20:25:08 UTC
From: Floyd Sense <sentek@sprintmail.com>
Message-ID: <E0xu5.34432$C42.1528556@newsread2.prod.itd.earthlink.net>
Source record: 181207

Early this year in this newsgroup, I asked whether or not other users of the SGC-230 Pro model automatic tuner had experienced a problem similar to one I'd found. The problem involved a spurious low-level signal that could be heard moving up or down the band while receiving with the tuner active. At that time, I heard from six other users of the tuner who were having the same problem.

In June, I sent my 230 Pro back to SGC for analysis, complete with recordings of the mysterious signal. This past week, I heard from SGC and they explained that the spurious signal originates in one of the oscillators unique to the 230 Pro. Note that the Pro model includes a remote computer interface and they use an oscillator-driven 5 VDC supply in that added circuitry. I was not happy to hear that there is no engineering solution to the problem. This problem does NOT exist in the standard SGC-230 model - only in the 230 Pro model. So, if you have a 230 Pro with the problem, and your unit is still under warranty, you might want to begin the arm twisting with SGC or your SGC dealer to have your unit replaced with a standard 230. If you do that, be prepared to be without your tuner for a long time. Getting SGC to pay attention to your problem will not be easy and you'll have to be persistent.

According to SGC, the 230 Pro model was developed for a single high-volume commercial customer and they thought the features might be of interest to the general ham community. It didn't work out that way and that's why AES was selling them at a big discount a couple of years back.

Forgive me if this is off topic but....
I've been looking around at service monitors but I can't seem to find any comparison info between IFR, Motorola, Marconi, Stabilock, Wavetek etc. I can only find out what features each has. I can't seem to find out whether one is more stable, if one is easier to get parts for (not obsolete) etc. I like IFR because I've been around them. But I need to go with what's the best buy overall.
Any info would be appreciated.
Thanks
Jim

If you haven't tried one yourself, you are missing something.
Once you've tried it, you can speak from your own experience
about how much its performance is impacted by it's surroundings,
on how critical the tuning is, on how well/poorly it matches,
on how well/poorly it performs etc etc. To me, it is interesting
enough that I think you ought to try it, just for the fun and
learning. The damn thing works better than it ought to, based
on its appearance. I had enough success with a 2 meter DDRR
to schedule some more experimentation with it. If nothing else,
it revealed that my testing of it was faulty. If the antenna ends up
as a dog in my view, it will at least have helped me learn to test
a little better.

Chip is trolling and confusing (purposefully) the issue again with semantic
babbling.

For those that have forgotten, the issue is:

dB=20*log(voltage ratio), NOT 10*log(voltage ratio); V/m is Volts.

Hi Barry,

>How to build a UHF-VHF antenna, maybe you know a web-site with all the sizes and parameters of antennas, or maybe you can explain it here?<

Find a good University that actually teaches RF. Graduate and buy a current HP network analyzer. Start a company and manufacture UHF-VHF antennas for about 20 years. Sell the company for a huge profit and retire. Then, you probably won't be one inch closer than you are now (hi).

But, I'd start with the ARRL Antenna Handbook and work from there!

> Chip N1IR

Finally! I have a credential Chip respects, being 9 years less 4 days
older than he is. Thus, I'm not one of those no-'count "youngsters".

I hope no one will be misled by the statements he made.

A ratio of voltages, currents, or field strengths (volts or amps per
linear unit) is dimensionless, as Chip points out. When a ratio of these
quantities is expressed in dB, the correct definition is dB = 20 *
log(ratio) where log is a base-10 logarithm. 20 dB does correspond to a
voltage or current ratio of 10 -- and this time you didn't hear it from
a "youngster". You can find this in any, and I mean any, elementary
text, from the absolute beginner through engineering levels.

When a power or power density ratio, which is also dimensionless, is
described in dB, the definition is 10 * log(ratio). 10 dB corresponds to
a power ratio of 10.

The reason for this dual definition is so that when the power in a given
circuit changes by, say, 20 dB (a factor of 100), the voltage and
current also change by a factor of 20 dB (a factor of 10).

I think this was on the Novice exam. It's surely on the Technician/General, so I'm sure nearly everyone reading this newsgroup is aware of these definitions. I'm posting it just to avoid the remaining few from being led astray.

Source record: 181069

>From: fractenna@aol.com (Fractenna)

>I will say it again. You CANNOT convert a measurement in V/m into a POWER.
>You CAN convert into a POWER DENSITY.

Yes, but one can use 10log(PD1/PD2) to compare power two power density figures. One can also use 10log(E1^2/E2^2) where E1 and E2 are the values of field that one can use to calcuate a specific power density. 10log(E1^2/E2^2) = 20log(E1/E2).

When you consider again the original premise, that 27.5 V/m is 19.24 dB greater than 3 V/m, in every context I can think of, the correct formula is 20log(E1/E2). First, the comparison is at a fixed impedance (377 ohms free space), so the voltages can be compared directly in dB. Second, if one is at a specific point near an antenna and measures a field of 27.5 V/m, the power to the antenna would have to be reduced by 20 dB to obtain 3 V/m at that point. In the EM field, fields and power density are converted to each other all the time, as plane-wave-equilvalent power density.

In the cable-TV industry, the signal levels inside cables are often expressed as dBuV -- dB relative to a microvolt. 10 uV is 20 dBuv. The examples go on and on.

The premise that the ratio between 27.5 V/m and 3 V/m equals 10 dB would mean that 20 dB = 10 dB. This could never be correct.

This is perfectly correct if one is comparing voltage readings at the same point in the circuit, even if the impedance is unknown. 20log((V2/x)/(V1/x)) = 20log((V1/y)/(V2/y)).

True, unless one takes the /m literally. V/m can give the amount of power in a
1 square meter area.

But again, in case anyone is not following the multiple threads, power
densities can be compared using 10log(PD1/PD2), 10 log (E1^2/E2^2) or 20 log
(E1/E2) where E1 and E2 are the V/m fields being compared. Using those formula
will give the same answers and as the power to the system is varied, the E/m
fields (or the A/m field, for that matter) will correspond exactly. That is
not true if one assumes that the ratio between E1 and E2 is 10log(E1/E2).

Hate to tell you this, but NEC-2 and the EZNEC program you use (as well as all others), use 20 * log(Field strength ratio) to calculate the dBi gain figures they report(*). Good thing, too. By your definition, the gain of a dipole over isotropic would be 1.07 dB.

For one of many examples of the use of 20 * log(field strength ratio) to express gain in dBi, see Kraus, _Antennas_, Second Edition, p. 443.

In the far field, field strength (volts/meter or amps/meter) is easily converted to power density (watts/square meter) by using the impedance of the medium (120 * pi ohms for free space). Power densities are converted to dB by using 10 * log(power density ratio). Thus a 20 dB power density change (a factor of 100) corresponds to a 20 dB field strength change (a factor of 10).

You might want to go back and re-evaluate some of your antenna gain claims in light of this information.

Roy Lewallen, W7EL

(*) In NEC-2 and -4, the actual calculation is 10 * log((FS ratio)^2) = 20 * log(FS ratio)

Is this saying that you do not believe that the relationship between 30 V/m and
3 V/m is 10 dB? :-)

V/m can be represented as a power density by squaring the field, which can then
be compared using 10log(PD1/PD2).

The physical quantity you have is VOLTAGE density (actually a voltage gradient in 1 D) The difference between these two values is about 10 dB in V/m.

You may square these accordingly and get POWER density, in which case there is about a 20 dB difference in w/m^2.

You will never, ever get power differences from these measurements.

I fully uinderstand what you were TRYING to say: that's not the issue.

The issue is WHY over a dozen hams will ignore the dimensional analysis and say incorrect things.

Very troubling.

>It is quite relevent to compare ANY two measurements (in the same units) and
>give the ratio as dB. It is also common engineering practice.

I don't recall that I have ever seen dB used in a context that was not related to power, other than seeing it sometimes used incorrectly to compare voltages measured in different impedances, or perhaps rarely to compare some specific amplitude, such as the amount of movement in a shake table. For example, I have never seen one say that there is 3 dB more water in one jar than another, or discuss a 3 dB change in velocity or a 3 dB change in resistance.

Can you give us examples of the proper use of dB in contexts other than amplitude or power?

>Expressing ratio in terms of dB does NOT imply you are comparing power.

Unless I am wrong, the definition of the Bel is a power ratio. Anyone have an IEEE dictionary handy? I am at home and don't have one.

>One does need to take care to apply the correct multiplier, i.e. 20, if the
>base unit is Volts, as in V/m.

I have never seen any multiplier other than 10 for power or amplitude^2 or 20 for amplitude. Can you provide any examples of others?

This is correct. But irrelevant. It's a deflection from the point of the discussion and your original statement. The contention is how to define, in dB, a ratio of field stengths. Universal usage (by Kraus, modeling programs, and all other references I know of) use 20 * log(field strength ratio). But you claim the correct formula is 10 * log(field strength ratio). By your definition were used, doubling the power to an antenna would increase its field strength by 1.5 dB, and the power density of the radiated field by 1.5 dB. I'm sure glad you're the only person using this definition!

Gee this is silly.

If you are using voltage ratios or current ratios to get power ratios then obviously there is a 20 log factor involved. That has nothing to do with comparing two values of V/m and expressing them as a dB difference.

dB does NOT NECESSARILY refer to POWER.

I think we are changing gears here a bit, Chip. I was not trying to say that power density is the same as power, just that power density can be derived from V/m and that it can be compared in dB by 10log(P1/P2).

>I am a bit taken aback when Ed says how wrong I am--that you CAN get
>POWER--and then in the next sentence calls it a POWER DENSITY.

That is not what I intended to say, Chip. I believe that you are wrong when you say that 10log(E1/E2) is the formula to use to compare electric field strengths. I showed the relationship between electric field strength and power density to explain why 20log(E1/E2) is the correct comparision.

Sorry for any confusion.

Sorry, Chip, I won't let you get away with steering the topic to the question of whether power can be derived from field strength alone. Of course it can't. We all know that. And we all notice that no one has been arguing that point. The point regards expressing a ratio of field strengths in dB. Please address that issue.

Good technique, though. Have you considered a career in politics?

>>73,
>>Ed Hare, W1RFI
>
>Since neither measurement gives POWER, your definition would require that dB is
>not an acceptable means of description.

Not at all. As I explained my post (as well as have many others) it
is quite correct to use dB to compare voltages provided that any
differences in impedance (not applicable in Hare's example) are taken
care of.

>In fact, dB is used for purposes other than describing power.

Please name one. How about dB$? But money is power, so there you
are.

> In this case,
>there is the almost 10dB difference in v/m. From this ONE CAN GET THE POWER
>DENSITY which is about 20dB..you figure out the units:-) It ain't watts!

Incorrect. You are just going to have to admit that you have made an
error here. There is no way that there is a 10 dB difference in v/m
in the above example. It is 20 dB. You are wrong.

No one is saying that watts are being calculated. What is being
calculated is relative power. There are no units - the units got
divided out because they were the same. v/m over v/m is unit-less.

>Dimensional analysis lives:-)!

Yes, it lives somewhere, but not, apparently, in your head.

Not long ago, someone suggested that he might avoid Fractenna products
on the basis of his observations of Chip's behavior. This might or might
not be justified or reasonable. But as an engineer, I'd surely look
carefully at any gain claims in light of the fundamental
misunderstanding expressed here.

I've had enough. You are hopeless on this.

Klein said that dB ONLY refers to power.

Thus it cannot refer to power density. WHAT I WAS ILLUSTRATING was that if
refers to ratio of quantites besides power.

Hi, Tom,

I started a more detailed response yesterday at lunch, but got sidetracked by the end of my lunch break. :-) I will finish it Monday, though I do not have a good answer to the main question.

The one thing that occured to me in reading that paragraph was, although I can't think of any reason that on 160 M, DX signals would arrive primarily vertically polarized, if they did, based on your hundreds of tests, you would see the vertical consistently stronger, or at least about equal to the dipole, but with normal fades from time to time as the polarization rotated towards horizontal. On the dipole, at least some of "fades" would be enhancement and you would see the dipole at least occasionally show an increase in signal as the polarization rotated horizontal. This would probably be swamped by normal propagation variations, and I don't think it at all likely, but the absence of the phenomenon may well be one point against the waves being predominantly vertically polarized.

I'm still thinking about all this; this is a very interesting problem! Thanks for bringing it up. It has brought me 20log(Joy1/Joy2) worth of enjoyment. :-)

Jim Pennino said
>
> dB=20*log(voltage ratio)
======================

ONLY provided the two voltages forming the ratio are with respect to the same impedance, resistance or load resistor, etc, which is frequently not specified because it is obvious from the context. And the same applies to dB = 20*log(current ratio).

10*log(power ratio) is without reference to anything except two power levels which may be in two different circuit or system locations. Eg., at the input and output of an amplifier having a load impedance entirely different from its input impedance. A power gain can occur when input volts is greater than output volts as in a cathode or emitter follower.

Well, it ain't normal feedline losses. TLA.EXE predicts 1.05 dB loss for the nearest equivalents in the program (9913 for the LMR400 and 3/4" 75-ohm hardline).

The NEC model has been around for years, and as far as I know, I have not heard of any such poor correlation for vertical antennas. OTOH, any feed line problem, or antenna problem, would certainly be reflected in the SWR and I really can't see what would have to be about 6 dB of loss in the feedline, not at all probable. Still, have you ever measured the power at the top of the tower?

Man, you spent a fortune in feedline alone; I can see why you are disappointed.

>A series capacitor works better in antenna leads at the TV.

This is probably a bad idea in some of today's cable installations. If the problem is common-mode pickup, one would need to use two caps, one in the shield and one in the center conductor leads. Their value would have to be small enough to act as a high pass filter, in which case, I would have to ask, why not use a high pass filter?

Even that can be problematical for coaxial cables, because the 75-ohm HPFs don't filter the shield -- there is the common-mode problem all over again.

There are techniques to install HPFs in coaxial cables that also act as braid-breakers, but modern cable TV is starting to use the HF range for communciation between the cable box and the central office (another RFI problem in the making -- I call it job security), so a high-pass filter in a CATV system may cause problems. That box or the office may decide it has been too long since they heard from each other and your cable service may go to sleep.

>Actually the single most effective cure for TVI is shunting the common
>mode current around the TV, rather than try to stop it. That works the
>vast majorty of the time, and costs a few pennies.

Yes, grounding the cable just outside the house may help, but that can create ground loops that will really get ya' when there are nearby lightning strikes and in apartments (and even some houses) it is not always practical. And the cable wiring after the ground may pick up RF all over again.

I still prefer the common-mode choke. Palomar sells them by mail order.

Ed:

You are absolutely correct and as usual Chip is WRONG (OK, maybe only reckless!)

The bel named after Alexander Graham Bell is defined in all "standard" electrical Engineering handbooks, textbooks, references encyclopedias and dictionaries as a logarithm of the ratio of two POWERS, nothing else!

Any other use of Bel and deciBel is thus non-standard.

That being said, all are permitted to go to hell in their own way, and dear scientist Chip, if he so desires can define logarithmic measures any way he wishes, he just can't claim that it is standard usage!

Next I suppose that he will want to change the standard definition of pH to be based upon a ratio of quarks, and get the chemists in an uproar.

[pH... A logarithmic measure of hydrogen ion concentration (a molecular ratio) in a solution.]

Hope this helps...

Thread:

A volt is a volt (Actually a Volt is simply a Joule per Couloumb, the measure of energy carried per unit charge!) and a rose by any other name would smell the same.

What power is being measured by a Volts per Meter meter? ???

"in"???

What is a measurement "in" V/m??? Really Chip!

"of"

A measurement "of" V/m perhaps, but "in"!!! Really Chip! I'm ashamed of you... loose speaking, fuzzy thinking! Is that what they teach at Cornell?

And... the act of measurement is simply the record of a value read from some instrument, which may or may not be actually measuring the quantity desired by the metrologist.

Often in Engineering, indirect quantities are measured from which are inferred other derived quantities. Stress is measured by a strain guage, etc...

This is not a "conversion"!!! What????

Most field strength instrumentation is not actually measuring power and everyone knows that, except apparently Chip. A bolometer measures power, but most other field strength instruments do not measure power. We all know that!!! Except Chip, who now forbids us to "convert" it to power!!! Heh, heh, glad he's not running the Supreme Court!

A metrologist taking a reading of volts/m, or any other quantitiy for that matter, may do as they wish with the numbers once the value is recorded. for instance they may use other quantities together with dimensional analysis to "convert" said reading to another quantity.

Who, or what, will prevent them from doing so???

What exactly is Chip's point? Other than the usual obfuscation! I

I'm sure glad I didn't have to sit in his BU classes!!! If he ever had me and my classmates as students we would have fried his butt and handed it to the Dean!!!

Well I asked Mary, and she told me that chemists are nothing more than
cooks!

However Chem E's are well gronded and Chem E's will know about pH and the
logarithm of the ratio of molecules.

But then Chip will have to define the square root of a molecule? What is
that a fractal?

Klein:

Exactly so....

End of discussion.

Chip will not be able to produce a single referece where the Bel or deciBel
is not defined in terms of power.

He appears to be extremely deficient in his knowledge of electrical
Engineering practice.

I do not take what I said to mean that use of the decibel to describe
ratios of power density would be improper. In fact, in my field, we
use power spectral density comparisons in dB all the time. It is
still fundamentally power that is being compared. I also believe that
W1RFI is quite correct is his use of dB with v/m. And you are wrong.

Last post from me on this one. Hopefully, last post from everyone
(except Chip, of course) as we've all said enough to convince everyone
but Chip. Besides, I've got to finish fixing my 10 element 80 meter
wire beam so I can work some VK's tonight.

Good DX,
Klein Gilhousen, WT6G

Just curious...

Why would Chip deliberately schedule an open house at his place when the
"latter day saints" are holding a big open house right next door?

Who was first to announce? The saints or Chip?

Anybody know?

1741. Antenna measurement short course

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-09 23:37:33 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <39BAC9BD.22A3C90A@eznec.com>
Source record: 181108

I just got a flyer advertising a 4-1/2 day short course titled "Far-Field, Anechoic Chamber, Compact, and Near-Field Antenna Measurements". It's at Georgia Tech, December 4-8. It sounds very complete, and should be of interest to anyone professionally involved in antenna measurement. You can see a course description at http://www.conted.gatech.edu/courses/wireless_and_antenna/EE-107.html.

Bob:

Yes, heres some pointers.

By experiment I found that when laid on the ground or in shallow (approx 1 inch deep) trenches in sandy soil such counterpoises/radials are usually almost 1/2 as short as free space calculations would require (1/4 wave) and so I usually start at about a physical 1/8 wave. I think Reg Edwards told me that he has a program that can calculate the "proper" length of radials laying on typical realistic grounds. I actually "tune" my radials "in situ".

I have done this a few times at a couple of different QTH's and by my operating results it seems to work well.

I usually put out the counterpoises to "fit the lot" and so they are not directly radials stretched straight out from a central point, only some are.

Instead they usually have to follow the house foundation line, garden beds, fence lines, etc...

I usually start with the first one a little longer than I estimated that I need and put it out first.

I then fire up the transmitter on the "desired" frequency, and then I measure the current in that counterpoise/radial at the feedpoint, then go out and cut a few feet off of it. Leave the rest of the wire in the ground though in case you have overcompensated and need to re-attach it. Return to measure the current at the feedpoint and then continue doing this until you reach the length that yeilds maximum current. If you over compensate and cut it too short, simply go out and solder the latest cut back on. Then when you consider it "tuned", go out and pull the rest of the cut off wire out of the ground.

Then go on to the next counterpoise or radial and repeat.

For my "stealth" inverted "L" antennas, I usually put out one tuned such radial/counterpoise per band/frequency that I intend to use. More than this won't hurt anything and may improve operation. In a couple of locations I have done this for up to 5 bands, and thus have put out up to 5 - 10 "tuned" counterpoises. It makes a nice "all band" invisible all band antenna and seems to work well.

Inverted L fed at the base from a good high power tuner fed against several hand "tuned" radial/counterpoises buried in the garden or lawn.

Simple cheap, can be all built and tuned in one Saturday afternoon, about a six pack of beer job.

Usually I have strung the inverted L up a big pine tree or a chimney and
then run it over across the house roof to another tree, etc... I have done
this in two locations where antennas were forbidden by covenant. I used
small guage wire and hid it all in the trees and lawn, ran an "all band" HF
station and no one was any the wiser. I got good signal reports, much
better than from those "store bought" trapped verticals.

The "tuned" radials/counterpoises always seemed to make a big difference in
performance.

I would never buy or use one of those "store bought" all band verticals, use
the cheap high performance tuned inverted L instead.

But Chip, I didn't say any gain claims were incorrect. Apparently you didn't read my post.

What I did say is that because you have such a fundamental misunderstanding of the use of dB to describe field strength ratios, I would look carefully at any gain claims you might make. If you applied your faulty dB calculations to measured or caclulated field strengths, the results would be in error. For example, you would conclude that increasing the power to an antenna by 3 dB would increase the field strength by 1.5 dB. Or let's take the same numbers which started this whole thing. To increase the field strength from an antenna from 3 to 27.5 V/m would require increasing the power fed to the antenna by 19.24 dB. Yet you have said that the field strength difference is only about 10 dB. And you stand by your statement. So there's also a likelihood that this reasoning will also be applied in the future. If it is, the results will be incorrect.

This is an outrageous piece of propaganda. It has no accuracy or rlevancy to
even a remote attempt of extrapolation from my comment to W1RFI's post.

Put simply it is not only wrong, but targetted to be destructive.

What exactly, Mr. Lewallen, is your agenda in this ?

Hi Mike--

I wish you and her well, and if you have anything you think I can help with on antenna info, feel free to correspond via e-mail; I will happily reply.

Best Wishes,
Chip N1IR

Those of us who have been on the newsgroup for a while have all learned to be cautious. The only reason I bother posting in response is that people who don't know his track record might be misled. Certainly, I and all veteran readers know that no matter what anyone says, Chip won't ever, ever, change his mind or admit to an error, no matter how obvious or well documented it is. So any posting trying to convince him of anything is a total waste of time and effort. But hopefully the lurkers will learn from both the tone and content of the resulting exchanges.

Because the Temple Open House goes on until the end of September; October brings contest weekends and travel schedules for the remaining fall; and because I planned it back in My--before I knew about the LDS Open House. Finally, because no one has asked us to in any way compromise our enjoyment of life because of our neighbor's exciting events. Good luck LDS folks and congrats!

>What I did say is that because you have such a fundamental
>misunderstanding of the use of dB to describe field strength ratios,

Stop right there. That is incorrect. Furthermore it has aboslutely NO RELEVANCE or BEARING.

Demonstrate JUST ONCE that I HAVE INCORRECTLY REPORTED a field strength measurement or model value.

Just once.

Show how my value differs from yours.

This is a deliberate diversion which you produced to undermine me and Fractal Antenna Systems,Inc.

Whate ever happened to "No more public talks for HAMs" or whatever the
other posting was about?

Or maybe he's edited and printed out excerpts from this NG, and
convinced the police in his area that he's being "stalked" online, and
this is just a trap to lure the unsuspecting out so that they may have
a police record, which would give Chip the ability to say things like,
"Your opinions are unimportant, you are a criminal."

Hrm... Just food for thought.

Chip:

Thanks, I know from personal experience that sometimes the LDS can be "annoying", but it usually doesn't last long if you let them know they are doing it.

I have worked with, and have hired and supervised, several LDS Engineering graduates who graduated from the EE programs at BYU and U of Utah.

As an educator you might be interested in the following observations.

IMHO... opinion those two schools which contain a preponderance of LDS students produce excellent Engineering graduates and the folks who graduated from those programs that I have worked with had some of the best work ethic I have ever seen in the Engineering community.

Those two schools have simply great undergraduate Engineering programs, others would do well to model their programs after them.

Maybe we should all "chip" in and send Nate. He might learn something and it would give the group a respite from his posts for five days. But then we might have to send Phil and Cohendog too... This could get expensive.

Do they have a group or family discount?

Haven't measured power up there. You can bet that I won't either!

>Man, you spent a fortune in feedline alone; I can see why you are disappointed.

Well, just this morning the dipole tied the vertical. No difference.

NEC could be fine. It could be the wave is mostly vertical, or it
could be the wave angle is low.

Let me toss something out. Don't some of the NEC engine programs
calculate FS at extreme distances? Are those distances approaching the
height of the ionosphere? Do they consider the earth flat?

What about the distance used to describe the pattern. Could it be too
far away for the real world?

I have no problem with what you have stated. Now all we have to do is
to get the antenna makers to decide what DB they are using. One even
adds the ground reflection gain as an antenna modling program predicts
to a vhf beam for added advertising gain.

I have a serious question.

How can you tell the difference between Chip and a refrigerator?

Anyone?

More cleverly worded bullcrap.

Read carefully folks. What he is saying is over the past many years on all bands, he has managed to work 310 countries (big deal) using other antennas.

Now he worked one new DX station with his pathetic FQY, and want's us to believe he did it with one call.

1768. Definition of dB

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-10 00:55:59 UTC
From: fractenna@aol.com

I will be brief and to the point--accurate and honest.

A dB is a means of representing the logarithm of the ratio of two quantities. In most EE applications, those quantities are power, or are meant to relate to power ratios as extrapolated from the observable--such as voltage.

However--

It has become common practice to adopt the dB scale in cases where POWER is NOT being discussed. It becomes a convenient representation to indicate dynamic range or change of two quantities of the same observable.[Ed, W1RFI, indeed uses it for power density. This is NOT power.]

If one wants to COMPARE TWO VOLTAGE DENSITIES as a DIFFERENCE--such as Ed discusses-- then there is neither relevance nor accuracy in discussing POWER.

If there is an order of magnitude difference in two VOLTAGES, this is a 10 dB difference between the two. But it also represents a 20dB difference in POWER when extrapolated to such.

I hope that people understand where the 10 and 20 come from in the log formula--the 20 is used when voltages or currents are measured--and a POWER ratio is being considered (you have to square in Ohm's law to get powers, thus squaring raises the 10 to a 20). Otherwise, to indicate a sense of the dynamic range of the observables alone, the 10 is used.

I am deeply troubled that the dB scale has become some sort of memorized hocus pocus, as opposed to a simply derived and useful idea..

All I have just said rerpises and slightly expands what I have already proffereed; glad to be of help.

1769. Two reflectors- again!

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-10 01:09:14 UTC
From: Bill Aycock <baycock@hiwaay.net>
Message-ID: <39BADF3A.953F4274@hiwaay.net>
Source record: 181036

Last week (subj:"Unwin lives") I reported on the results of EZNEC runs on Arts' double reflector, long boom antenna. This was just a few runs, using the great (intuitive feed) EZNEC Windows program, and the two files that had been prepared by Roy from Arts' input.

In summary- the high front-to-back ratio (~40) on both single and double reflector models, the effect that the second reflector had on bringing the SWR WAY down, and the double nodes (15 and 45 degrees) and deep null (30 degrees). All-in-all, a very interesting exercise.

THe big difference between the 'free space' and 'real ground' runs was, as expected, in the pattern distribution. The lobes of the 'real ground runs were quit useable, but probably far from the best. Art had used a height of 820 inches in his original file.

Tom, N4KG, a pretty good all-band DXer from just to my west, is always glad to tell people that 'higher is not always better'. Following this, I used the easy change features of the input of EZNEC, and tried several different heights. I am glad I did- the results are good enough to lead me to explore this some more.

The bottom line is that the second (upper) lobe almost disappears at lower heights, the low SWR is preserved, and the F/B goes up to about 50, at a height of 400 inches. The major lode is at about 20 degrees, and can be varied by height changes.

My look-see is far from complete, but Art appears to have a pretty good, well matched antenna. It will be interesting to see what the real version does. Maybe I can get him to try it lower.

OK, here's one with a reference; lot's of fields other than electronics use
dB.

"0db SPL is a wave whose rms pressure is 0.0002ubar (a bar is 10^6 dynes per
square centimeter, approximately 1 atmosphere)"

From: The Art of Electronics, Horowitz and Hill

This is, BTW, a good book to own.

To be pendatic, you are correct when you question contexts other than amplitude
or power. But there are other "things" that have amplitude besides Volts.

Well on second thought, with your connections, I'm sure you could get a government grant to pay your way. Of course, we are the government--at least at pay-up time--so I guess we would have to pony up either way.

But there is a third option. You pay your own way since you want to visit Tom's place anyway. And while you're there---since he's needing someone to carry a power meter to the top of his 300 foot tower to make some 10*log (p1/p2) measurements for Ed Hare---maybe you could volunteer.

I sure Tom would be happy to have you do it. He'll loan you the used climbing belt he just bought on eBay and I'll bet that with only a little encouragement, Tom could be induced to key his "experimental" 10 KW rig while you are up top so that you could test your new-found knowledge of "near-field" measurements. I believe that a cooperative effort like this is just what is needed to patch up the differences you fellows have with each other.

Additionally, if your climb happened to coincide with one of Georgia's famed thunderstorms, you could test the veracity of some of Tom's claims about lightning protection and grounding. I imagine that a physicist with your credentials would "jump" at this opportunity.

What say guys?

No, No, Peter; you don't understand. In the good old US of A, it is unacceptable for anyone to have something which someone else does not have. Therefore, anytime anyone works his butt off and acquires something the old fashioned and honest way, automatically there are those who step forward and claim the same prize. Most often society, and in recent years our government, agrees and declares that the claimant will also have the same reward.

I saw a post just recently where someone actually claimed the government kept them out of ham radio for some great number of (was it 40?) years because the government had requirements relative to receiving a ham license!

We are very close to the long projected and expected status of things being run by the freebanders!

Chip, N1IR wrote:
"If you are using voltage ratios or current ratios to get power ratios
then obviously there is a 20 log factor involved."

Volts per meter have exactly the same relationship to watts per square meter as
volts have to watts. Chip`s point may be that meters versus square meters are not the same as volts versus watts. He is mistaken if he thinks this is significant in our discussion.

From the inventors of te decibel, AT&T, and their Principles of Electricity",
"---the new unit, called the decibel (abreviated "db"), represents always a fixed percentage reduction in power no matter what frequency is involved.----
No. of db = N = 10 log P1 / Po
or
N = 20 log I1 / Io
Although in the above we have been considering the decibel in connection with measurements of loss or attenuation, it is equally useful in the measurement of gain such as that given by a telephone repeater.----"

John Cunningham in "The Complete Broadcast Handbook" is plain spoken. He says:
Voltage is equal to the square root of the power times the resistance. Thus we can say that the field intensity in volts per meter is given by the square root of the watts per square meter, then multiplied by 377 ohms.

NEC considers the Earth to be flat and infinite in extent. The far field is calculated at an infinite distance. (As I recall, MININEC uses an actual distance of 10,000 km.) I don't think the height of the ionosphere should have any bearing on the results.

> What about the distance used to describe the pattern. Could it be too
> far away for the real world?

I don't think so. The shape of the field is pretty much the same at a wavelength or two as it is an infinite distance away. So choose any distance within that range, and the shape won't change appreciably.

A number of users have noticed that the ground wave results reported by NEC (and EZNEC pro) diverge from the FCC curves beginning at about 100 km. This is due to the flat-Earth approximation. But the standard version of EZNEC only reports the sky wave, and I don't think the ground wave is important to the questions being asked here. Certainly by the time you get a couple of hundred miles away, including the ground wave would make no appreciable difference to the result.

On or about Sun, 10 Sep 2000 00:48:10 GMT, 2w8ji@contesting.com (Tom W8JI), using the forum rec.radio.amateur.antenna did say:
:
:I have a serious question.
:
:How can you tell the difference between Chip and a refrigerator?
:
:Anyone?

1. It's easy to find out how a refigerator operates.
2. Almost anyone can open a refrigerator.
3. The lightbulb in the refrigerator actually comes on once in awhile.
4. The refrigerator has a purpose that most anyone can agree upon.
5. The refrigerator behaves exactly the same way every time, unless something is wrong with it.
6. When something is wrong with a refrigerator, it can either be fixed, or thrown away and a new refrigerator obtained.
7. If you don't like its color, you can paint it.
8. Most people appreciate a refrigerator.

I'm sure I'll think of more.

>From: fractenna@aol.com (Fractenna)

> It becomes a convenient representation to indicate dynamic
>range or change of two quantities of the same observable.

In the case of dynamic range, it is indeed a power or voltage in the same impedance comparison; dynamic range is the difference, expressed in dB, of the weakest signal a receiver can hear and the strongest signal a receiver can accomodate.

>Ed, W1RFI, indeed uses it for power density. This is NOT power.

No, but in comparing power density, one is comparing a power ratio. 10log(P1/P2) = 10 log((P1/x)/(P2/x) = 10log((P1/(x^2))/(P2/(x^2))), etc. (Sure hope I got all the parenthesis right.) To use decibels in a comparison that has power as a factor, one does NOT need to know the exact power level; if the mathematics of that comparison are such that a ratio of power is involved, then 10log(P1/P2) still applies.

I think we are in agreement here.

>If there is an order of magnitude difference in two VOLTAGES,
>this is a 10 dB difference between the two.

Chip, this is just plain wrong. I know of no kind or other way to say it. Other than in this thread, I have never seen a single reference that indicates that dB = 10 log(V1/V2). I have seen hundreds of references indicating that if the two voltages being compared are being measured across the same resistance, then db=20*log(V1/V2).

>the 20 is used when voltages or currents are measured

Well, yes, (if the impedances are equal)so why do you keep saying that 10 is used when voltage gradients are compared?

if dB = 20log(V1/V2) it also equals 20log((V1/m)/(V2/m)); try it with a calculator for different values of M. Any ratio of voltages, however derived, are represented by 20log(V1/V2), in a system where the impedances are equal.

I cede the point about dB and sound pressure, which, btw, is related to a power ratio, but acoustical power, not RF power, but I have never, ever, ever seen dB used to compare plain numbers. It simply is not in the definition. And trying to tell us that because V is divided by m, one uses 10log(ratio) but if V is not divided by m, then 20log(ratio) just doesn't make any sense at all.

Again, in the case of comparing exposure levels, if one goes from 30 V/m to 3 V/m, the change is -20 dB. The power density will be decreased by 20 dB; the applied power must be decreased by 20 dB; the applied voltage to the antenna

will have decreased by 20 dB.

I think, Chip, that your view that the dB function applies to pure numbers has led to some confusion on how and when to apply it as it relates to a voltage gradient. It is a term that can be applied to power, or to amplitude squared, but your assertation that dB = 10log((V1/m)/(V2/m) but that dB = 20log(V1/V2) does not work with my calculator.

>All I have just said rerpises and slightly expands what I have already

I'm not sure about that Roy.

If I look at farfield pattern in the model at infinite distance, a
vertical has no groundwave signal over real earth. If I look at the
real-world pattern at 20 miles, the groundwave field strength is
appreciable. At 10 miles, it converges even more towards the the
higher angle radiation.

If I look at it at two wavelengths, there is virtually no additional
attenuation along the ground.

It seems reasonable to me that if the height of the ionosphere
approaches the distance where the earth hasn't attenuated the signal,
there might be more low angle radiation than expected.

I know I am overlooking some factors, but has the pattern actually
been measured at ten miles distant (or other distances) at various
heights above earth to see if the pattern tracks?

It would seem like the pattern would be accurate as you go up in
frequency, and earth losses increase greatly with distance.

>From: 2w8ji@contesting.com (Tom W8JI)

Bear with me, Tom; I am just musing here with you. Do keep in mind that most of my knowledge of antennas comes from doing a fair piece of EZNEC modeling, both far-field and near field. And, of course, one of the things that is under consideration here is how well the modeling applies to this real-world antenna situation. But it is a fun conversation. :-)

>Don't some of the NEC engine programs
>calculate FS at extreme distances?

Roy probably knows more about this than I, but the pattern is very clearly far field.

>What about the distance used to describe the pattern. Could it be too
>far away for the real world?

I expect not. The far field distance of 2D^2/lambda should be accurate for the gain of the antenna, except at the very lowest angles. And, though I might accept that even on 160M, a long-haul DX signal might be coming in at angles lower than one might think, I do recall seeing a chart so many years ago that indicated that the signals on the lower HF bands from Europe, to I believe W1, were coming in at 20-40 degrees. I would expect that, for a number of reasons, most 160 M signals are in that general range.

The theory about the far-field pattern distance being too far could probably be tested using EZNEC's near-field pattern to get the pattern nearer the antenna, say 1 km away. It should, if my understanding is correct, match the far field pattern pretty well. It would be a laborious run, though, becuase one would have to select that X,Y,Z coordinates and either run a really big matrix then look for the correct ones to give a pattern or do them one at a time.

Besides, your tests indicate that the disparity is heard on signals that are at a wide variety of distances, which presumably would include a wide range of incoming angles. And at the higher angles, that vertical will be working nearly as good as it would over perfect ground, considering the low ohmic losses in your radial system.

I thought some about the additional structures around your antenna. I don't think they are involved. First, the description you gave doesn't appear to be one that would absorb and not reradiate energy. If they were functioning as parasitic elements to that 80 M antenna, the description doesn't sound like it would create a cloud warmer, so if they had an effect, it would be to make the antenna a bit worse in some directions and angles and a bit better for others. Your tests indicate less performance than you had expected for all directions and angles.

keep coming back to loss, somehow; that is really the one explanation that makes sense. But I don't think it is loss in the feedline, at least not ohmic loss. The coax you use calculated to be about 1 dB loss. I can't think of any reason that it should be more lossy than that in a uniform way that doesn't affect the SWR, and a blatant defect WOULD almost certainly affect the SWR. Maybe, for some reason, some of the signal inside the coax is getting converted into a common-mode signal on the outside of the coax, but the baluns should really take care of that and I just can't imagine 4 to 6 dB of "loss" by that mode.

>Haven't measured power up there. You can bet that I won't either!

I guess you don't climb the tower very much. I don't blame you. But there may be a few ground techniques that you can try. Do you have a copy of EZNEC, BTW? If so, once you model the antenna, EZNEC can predict the complex impedance at the antenna over a wide frequency range. You can analyze the impedance measured at your station, after calculating the effect of the feed line, and determine if it varies as expected, or if it varies less than expected. (Knowing the length of the feed lines precisely would help a lot). I have done the first parts of this -- the EZNEC run and the TLA.EXE analysis; I can review some of the math in that Witt QST article to refresh my memory on how to estimate feed line losses from the results. I think that the MFJ-259 also has a feed-line loss function that may help. After typing all this, it does look like a lot of work, though, eh? :-)

Equally interesting are the results you indicate others with similar high antennas have seen. I just can't imagine all these experienced 160 M hams putting up lossy antenna systems.

OTOH, I really am at a loss to explain what is going on. I wonder if it would help to do some accurate FS measurements? I will chat about this off line, if it looks like that will be the only way to resolve this.

BTW, what is the length of feed line to the vertical?

> A dB is a means of representing the logarithm of the ratio of two quantities.
> In most EE applications, those quantities are power, or are meant to relate to
> power ratios as extrapolated from the observable--such as voltage.

Nope. In most EE applications dB power is used for RF stuff, db Volts for
other stuff. Look at any OPAMP spec sheet; the open loop gain is normally
given in terms of voltage gain, i.e. db Volts.

> However--

> It has become common practice to adopt the dB scale in cases where POWER is NOT
> being discussed. It becomes a convenient representation to indicate dynamic
> range or change of two quantities of the same observable.[Ed, W1RFI, indeed
> uses it for power density. This is NOT power.]

It has LONG been common practice to use dB for other than power ratios. Once
again, look at an OPAMP spec sheet. You will find a graph of 20*log(Vout/Vin)
against frequency.

> If one wants to COMPARE TWO VOLTAGE DENSITIES as a DIFFERENCE--such as Ed
> discusses-- then there is neither relevance nor accuracy in discussing POWER.

There is no relevance to this statement. Only Chip is hung up on trying
somehow to hang power on a voltage difference.

> If there is an order of magnitude difference in two VOLTAGES, this is a 10 dB
> difference between the two. But it also represents a 20dB difference in POWER
> when extrapolated to such.

Flat wrong. 20*log(10)=20, ergo 20dbV diffence between the two.

> I hope that people understand where the 10 and 20 come from in the log
> formula--the 20 is used when voltages or currents are measured--and a POWER
> ratio is being considered (you have to square in Ohm's law to get powers, thus
> squaring raises the 10 to a 20). Otherwise, to indicate a sense of the dynamic
> range of the observables alone, the 10 is used.

The first sentence is correct but overly wordy to say:

10*log((V1^2/R) / (V2^2/R) = 20*log(V1/V2)

The second sentence is plain nonsense.

> I am deeply troubled that the dB scale has become some sort of memorized hocus
> pocus, as opposed to a simply derived and useful idea..

The only confusion here is by Chip; the rest of us got it years ago.

> All I have just said rerpises and slightly expands what I have already
> proffereed; glad to be of help.

> 73
> Chip N1IR

I would suggest that anyone with an interest in electronics obtain a copy of The Art of Electronics by Horowitz and Hill wherein one can find clear, succinct, non-ego driven explainations of how electronic things work.

1802. Re: SPI-RO MFG TRAP DIPOLES

Newsgroup: rec.radio.amateur.antenna

One-Trap-pair Multiband Dipoles

Alan Biocca, WB6ZQZ, 9/00

I have been testing two two-trap multiband dipoles, the Spi-Ro, and the W2AU/W2VS. Both antennas use a 40 meter trap in each leg and are approximately 110 feet long:

0----------------trap----------------balun/feedline----------------trap----------------0

Sources - The Spi-Ro is avertised in QST, and the W2AU/W2VS is available from Amateur Electronic Supply.

Background - The parallel resonant traps isolate the central dipole on 40 meters (where is is resonant), act as inductors shortening the (whole) antenna on 80 meters, and act as series capacitors on the higher bands. By judicious selection of L/C ratios and wire lengths this antenna can be fed with a simple coax and achieve 3:1 or lower SWR on 40/20/15/10/6 meters, staying under 5.5:1 on the ends of 80 meters and the nonharmonic bands (SWR will vary somewhat with each installation environment). There are numerous examples of this type of antenna in the ARRL literature. The moderate SWRs are important both from the standpoint of compatibility with the (in some models) limited range of automatic tuners, and to minimize losses in the coaxial feedline that become significant if the SWR is high. This antenna has similar performance to the popular G5RV but is easier to match.

I originally started with a G5RV fed with coax/choke/ladder line and found the SWR varied so significantly that the autotuner in the IC761 could not handle it on some frequencies, and that eventually led me to the W2AU/W2VS antenna. It solved the matching problems and I used it for a number of years until the guy rope failed and the aluminum coil was ground through dragging on the asphalt shingles of the roof. I will use better guy line and insure that the coils are not allowed to drag on the roof in the future...

The Spi-Ro traps are PVC encased with brass screw attachments for the wires. The coils are necessarily small in diameter inside the PVC. I did not section one so I don't know the arrangement. There is a mark to orient the trap, so apparently the internals are not exactly symmetrical. Due to the PVC the traps are heavier than the W2AU/W2VS.

I constructed the Spi-Ro antenna with the recommended wire lengths: --20'8"--trap--31'9"-- balun --... I used #12 THHN wire, and the Spi-Ro 1:1 Current Balun in the center. I erected the antenna on a camping trip in the National Forest approx 30' up in a fairly flat vee with the ends supported 15 or so feet up. I attached 50' of RG8X and used a MFJ antenna bridge to measure the SWR on the varous bands. I'm sorry to say the notes I took are evading my search right now, but it was very squirrely on bands above 40m. This improved

considerably after I changed the feedline, detailed below.

Since these multiband trap dipoles are somewhat reactive on many frequencies the feedline acts as an impedance transformer. The instructions for the Spi-Ro do not mention feedline length, but the instructions I have for the W2AU/W2VS traps recommend some lengths that provide better matching on the bands above 40m. I changed the feedline to an 83 foot length of RG58 and re-tested the Spi-Ro antenna. The effect was fairly dramatic on the higher bands, and the resulting SWR was similar to the W2VS which will be detailed below. Note that the higher loss of the RG58 also helped to lower the SWR. In my final installation I plan to use RG213, which may increase SWR slightly, but will reduce losses.

The W2VS traps are aluminum and plastic, and the coil is exposed (though it is clear-coated). The capacitor is formed from different diameter aluminum pipes that apparently overlap in the center of the coil. The tubes are cast into a solid block of plastic and the coil is wound in grooves on the surface. There is a shorting adjustment apparently to resonate the coil that shorts about three turns on one end.

I constructed the W2VS antenna with the same type #12 THHN wire, using the recommended lengths: ---22'--- trap --- 32' --- balun --- ... The antenna was erected on a different camping trip, and it was stretched between two trees at approx 40' height. Due to the mounting and feedline weight it was slightly lower in the middle than the ends. Using the same 83 foot feedline and meter I measured the SWR across the bands:

MHZ SWR

3.50 5.3
3.61 3
3.77 2
3.755 1.2
3.84 2
3.92 3
4.00 4.6

7.00 2.9
7.11 2
7.18 1.7
7.28 2
7.3 2.1

10.1 4.8
10.2 4.9

14.0 2.5
14.2 2.1
14.35 2.1

18.1 3.9
18.3 4

21.0 2.8
21.45 2.1

24.5 3
24.6 3

28 3.0
29 2.7
30 2.8

50 2.2
52 2.2
54 2.3

These SWRs are all well within the capability of the built-in autotuners in my IC761 and IC746, and both antennas worked quite well as far as I could tell during on-the-air testing. I did not compare them directly on-the-air.

At some point I may do further testing, though for the moment I plan to erect the W2AU/W2VS antenna at the home QTH and use the Spi-Ro for portable use. The PVC traps are a bit better for portable use mechanically, since they get drug in the dirt frequently. One test that was planned but not completed is to check for temperature rise in the traps after a few minutes of continuous carrier.

I don't really know which traps produce the lowest loss. One the one hand we have the larger coils in the W2AU/W2VS traps, with a better length-to-diameter for good Q, but then there is the conductivity of aluminum, the shorted turns at one end, and the aluminum tubing capacitor in the center of the coil to potentially detract from the Q. The Spi-Ro coils need to fit inside the confines of the PVC pipe, which one would expect would reduce the Q as well. At 100 watts the traps would have to consume 25 watts each to make a 3db loss in efficiency, which should be easily noted by trap temperature changes. With the insulative properties of PVC I suspect that a 25 watt loss would lead to coil failure. I never noted coil temperature increases, though I did not perform the specific test. My suspicion is that loss differences between traps are likely not enough to be important from an on-the-air standpoint. Perhaps more important is power handling capability, weatherability, and life. The Spi-Ro PVC is quite heavy, perhaps schedule 40 or heavier, so it should resist sunlight for a long time. The W2AU/W2VS traps are aluminum - down to the screws and washers and I can say they do not seem to significantly corrode or degrade in 5 years at my QTH (Richmond, CA, not near the bay).

In practice these antennas work very much like regular dipoles. The shortening on 80 meters is very helpful when fitting them into my home QTH, while not enough to make a noticeable loss in efficiency (according to my modelling). The convenience of a single antenna that works on all the bands within the range of built-in automatic antenna tuners is significant. There are no grounding issues since the antenna is symmetrical, and this is enforced by using a current balun at the feedpoint. There should be some gain (in some directions) at the higher frequencies, since the whole length of the wire is carrying current.

Hello Peter,

There is nothing fundamental about the decibel. It is an engineering convenience, that's all. Another poster provided a reference from an ancient BSTJ where the decibel is proposed and defined. As they suggest, it is a convenient way to express power relationships. Of course, if you do it wrong, your systems, antennas, etc won't work as you would hope. Just like any other misteak. ;-)

I recall attending a technical conference maybe 5-7 years ago on the newly emerging PCS service. At one point, an attorney got up to speak who representing some companies having existing licences to operate microwave systems in the proposed frequency band. He stated that his clients would INSIST on obtaining 200 dB protection from the new services. Clearly, this man had all too recently been introduced to the decibel. This was the practical end to his speech because all the engineers in the place were literally rolling on the floor and laughing uncontrollably.

Klein, WT6G
p.s. The 10 el 80m beam is now working again. I needed to unwrap the feedline from around the tower that holds up one end of the wire beam.

1804. Re: 10 mtr antenna... Houston, we have a problem

Source record: 180971

OK... I think i figured it out. I used my Dad's antenna anaylizer and started triming. The resonate frequency was around 27 mhz, but the bandwith was really narrow, and only 2.5-3.0 :1 Not good, so I began trimming the whip, and frequency rose slightly but bandwidth was narrow. then I moved the antenna slighly positioned behind the bumber rather than next to the body of the suburban. To keep the antenna above the roofline I added a spring and 4 in chaft to the mount (at the bottom), thus raising the antenna and effectively adding some antenna length (about 8 inches) thus raising the two resonators (if that's what they are), or open coils. All of the sudden the bandwidth grew like crazy , so i trimmed the antwenna again and have between 1.7-2.5 :1 from 27.6 mhz to 29.6 mhz...

Thanks to all for the advise and comments, it gave me something to think about!

Ed, my daddy told me years ago, when arguing with a jackass; make sure he isn't doing the same. Chip knows he is wrong and will never admit it. It is a total waste of time to argue with him. He has neither the engineering background nor the logical mind required to accept the mathematical proof you so eloquently offered. A simple case of casting pearls before swine...

I need your guys help! After being out of amateur radio for 32 years, I'm getting back into it with some vintage Heathkit gear. Problem is CC&R's and Wife. I'm putting up one of those Spider antennas off of our rear metal fence which overlooks a canyon and which will serve as the ground. I know that it is not idea, but is really the best that I can do as I cannot run any other kind of antenna which will not be observed by the neighbors and wife. I've really got to keep the whole thing rather stealthy. Problem is that my wife just found this tube that I picked today from Radio Shack which claims to be able to bring your coax through the wall and keep the whole affair waterproof. She had a fit stating that " you are not going to be drilling any hole through our walls". Can you all out there help me out so I can find a simple way to bring my coax into my rig room without drilling holes ie through the window somehow? Life was much simpler at the age of 16 with my Johnson Viking Valiant and SX-101 and 40 meter dipole at my parents house! Thanks! Jim Hahn in San Diego

An order of magnitude difference in two voltages (across the same resistance) is 20 dB. This will result in a difference in the power dissipated by the resistance of 20 dB.

Well, I wouldn't be THAT blunt about it...

I think I'd point out that, if you're all stressed out, and can't relax doing your hobby, that you might have a heart attack at a young age, and then you woulnd't be around to finish up that honey-do list that keeps growing, or help remodel the kitchen.

Also point out that, without a hobby of your own, you might just have to join her needlepoint group, or her bridge club, or whatever other hobby group she enjoys. ::grin::

Just my two cents.

Wow. 280 dB is the ratio of the light output from a two-cell flashlight
to the light output from the Sun. 999 dB is a LOT of attenuation.

In practice, it's impossible to keep anywhere near that fraction of a
signal from getting around the attenuator one way or another. I don't
have a good background in metrology, but believe that somewhere around
80 - 100 dB is a practical limit for attenuators, for that reason.
Someone more intimately familiar with merology might comment further.

There has to be a way to bring the damn line through the window somehow; isn't there? Jim..... I just remember it not being so hard when my buddy and I were 16; we even put a Mosely 20 meter beam which we bought from Henry Radio in L.A. (1965) up on a homemade tower - until the tower crashed into the house next door; luckily the thing did not go through the roof of the neighbors house; then there was the time that we built a little shocker box out of Popular Electronics but being the intelligent kids that we were in 1966 we upped the voltage from 1.5 Volts to a 90 Volt dry cell somehow. The local Sav-On ice cream manager kind of jipped us on the size of one of the ice cream cones during the summer of 66 - we then proceeded to get behind him barely touching his elbow with said cone flying up towards the ceiling of the place with us barreling out of the store. It was so much easier then without mortgages, payrolls,..... Jim

Lots of hams install a 1x2 across the bottom of the window and
drill holes for the feedline. I prefer plexiglas myself.

Hi, I have an ICOM IC-746 and I just couldn't decide whether to use a vertical HF antenna or use an all band HF dipole, so I have decided to do both. I will use the GAP Titan DX, and maybe the Van Gorden All Bander that is sold for $29.95 I just have a few questions though. I am a new ham, so I don't know a heck of alot about dipoles, but is this All Bander antenna center fed, or is it fed at one end of it? Also, does the dipole have to run in a straight line because if I put this thing in my backyard, I would have to make two 90 degree bends to make it fit. Also, do I have to ground this antenna like I would the Titan DX? If you could please help answer these questions I would appreciate it. Thanks.

Yep, once you get to the 80 db or so range, the efforts required to keep signals from bypassing the attenuator become increasingly heroic; frequency does make a bit of difference.

I once had a minor involement with some people trying to construct an RF free environment; they had a underground shielded room inside a shielded room. As I recall, they got a bit over 100 dB from the outside world.

I would wager the attenuator in question actually goes to 99.9 dB and the 999 was a typo.

Jim,

I was just reading your query, and some of the other answers to it, to my wife.

She says drill the damn hole. Explain to your wife that the house has four walls. I believe that California is a community property state, so you own the place 50-50. She owns two walls and you own two walls. You're going to drill through _your_ wall. She can drill through her's or not as she sees fit.

Personally, I have a piece of 2" PVC through my wall and it's getting full. When I need to bring the 7/8 Heliax from the new EME array in, I'm going to put in another one beside it.

The downside to this is that it's hard to keep the scorpions from squeezing by the cables. The upside is that when you have scorpions in the house, you don't have a cricket or cockroach problem. Life is just full of tradeoffs.

Remember, it is easier to get forgiveness than permission. Drill the hole and then announce that you're taking her out to dinner. The dining room at the Coronado Hotel would be nice. Order the chateaubriand for two and a good bottle of champagne (Moet & Chandon R&#65533;serve Imp&#65533;rial would be a nice complement).

This will be expensive, but---and you can trust me on this---it will be a whole lot cheaper than a divorce.

I've got a fancy step attenuator with a range of 0 to 120 dB in one dB steps. At frequencies below about 50 MHz and using top quality cable, connectors, signal sources and measurement technique, it works reliably all the way to 120 dB. Above 500 MHz, I have never been able to achieve enough isolation external to the attenuator to verify operation with much more than 80 dB or so.

On or about Sun, 10 Sep 2000 05:58:42 GMT, n7ws_nospam@arrl.net (Wes
Stewart), using the forum rec.radio.amateur.antenna did say:
:
:The downside to this is that it's hard to keep the scorpions from squeezing by
:the cables. The upside is that when you have scorpions in the house, you don't
:have a cricket or cockroach problem. Life is just full of tradeoffs.

That spray foam insulation might help you keep the scorpions out...
just spray a thin "barrier" over the end of the pipe on each end, and
around the cables. When you need to add something, poke the insulation
out, pass the new cable, and reinsulate. It'll keep the scorps out,
the Air Conditioning in, and save ya a little bit of hassle and money.

:Remember, it is easier to get forgiveness than permission. Drill the hole and
:then announce that you're taking her out to dinner. The dining room at the
:Coronado Hotel would be nice. Order the chateaubriand for two and a good bottle

1829. Re: Hide your antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-10 06:33:11 UTC
From: Roger Halstead <rdhalste@tm.net>
Message-ID: <HWFu5.270$Qe.8782@newshog.newsread.com>
Source record: 180997

Nah.
It started with a discussion about the new (well not quite so new) exposure limits going into effect for hams.

I ran the following through the calculator, but make no claims for accuracy. I have been known to transpose. <:-))

It's not much of a limitation at all for low bands and wire antennas...Just a few feet.

A bit more for a tribander...Figure on 10 meters in that case with 1500 PEP with out processing is 20% and you transmit 50 % of the time (say 5 minute transmissions back and fourth) would be 1500 X 0.2 X 0.5 = 150 Watts average power...and a gain of 10 dbi the controlled area minimum distance is 17.88 feet and the uncontrolled area is 39.93 feet. Meaning if your tribander is at 46 feet and you operate SSB then your neighbor could stand under it at the base of the tower.

But if you operate CW which is figured at a 40% duty cycle...Using the same figures gives an average of 300 watts and the distances become 25 and 56 feet and these figures didn't even take into account the feed line loss.

Now if you operate a quadature array on 2-meters with 20 dbi gain and run the legal limit the distances start to become significant.

Say you run FM which is considered 100%, but you again run a 50% duty cycle in the 30 minutes and you run 1000 watts output, so we end up with an average power of 500 watts. That one creates some significant distances of almost 105 feet from the center of the antenna for the controlled area and just over 234 feet for the uncontrolled area. Course most of us do not run a fraction of this and a DXer running the legal limit on SSB comes out with a little over 57 feet for the controlled area and a bit over 128 feet for the uncontrolled area. CW results in about 81 and 181 feet when running the legal limit.

Good incentive for a taller tower.

Remember that these calculations produce a "worst case" and do not take into account the peaks and nulls in the pattern.

I didn't plug in anything for 220 and up, but the distances go up even more.

Best method...Move and get a different wife.
Might not even be the most expensive, but then again it could!
My wife always tells me that I'd find it difficult to fly half an airplane.
Says she'd take half the airplane rather than the money.

So, trying for a less stressful approach...There is the old flagpole
approach, or attic antenna. If stuck with the wire over the fence idea, I'd
bring it in underground, sneak it up under the siding (if you don't have
brick) and through the top of the plate over the foundation, or basement
wall.

Get a can of the expandable foam insulation and fill about a foot of the
pipe.
Move the cables around a bit to get them fully bonded to the foam. Most
critters don't like to dig in that stuff, but...don't put it out in the
sunlight as the UV causes it to break down and turn an dirty brown
color...Maybe paint any that shows outside.

1832. 3 legged dipole (tripole?) idea

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-10 06:49:10 UTC
From: Robert Casey <wa2ise@ix.netcom.com>
Message-ID: <39BB2EE6.C70C9F51@ix.netcom.com>
Source record: 181000

Could this work? Imagine a 3 legged dipole (tripole?) in a
horizontal plane, with 1/4 wavelength elements comming from
a central feedpoint, spaced 120 degrees apart. One leg
would be fed from the transmitter coax, then there is more
coax (1/3 wavelength) and that feeds the 2nd element, and then
another piece of coax 1/3 wavelength to feed the last element.
So you'd have 3 phases of transmitter power. This should
create an omnidirectional horizontal wave. And circular polarization
up and down.

You could use 3 wire "twin" lead instead of coax to feed the elements,
each wire being 0 degree, 120 degree and 240 degree phase shift.
Of course this will be a monoband antenna.

This the stupidest idea ever thought about on antennas, or what? :-)

1833. Re: 3 legged dipole (tripole?) idea

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-10 07:29:53 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <39BB3871.6C07C3E3@eznec.com>
Source record: 181001

Let's call the wires A, B, and C. The center conductor of the coax goes to wire A. Where does the shield connect? The coax that goes from wire A to B -- presumably the center conductor of one end goes to the end of wire A and the center conductor of the other end to wire B. Where does the shield connect on each end?

Crossed dipoles fed at 90 degrees have been used for ages to get this kind of pattern. It's commonly called a turnstile. An advantage of that configuration is that there's no coupling between the dipoles (in theory at least). So if a coax "delay line" is used between them, it sees as a load the impedance of an isolated dipole. With the proper characteristic impedance, then, the delay in the cable equals its electrical length. This wouldn't be the case if the elements weren't at right angles.

Roy Lewallen, W7EL

>From: "Roger Halstead" rdhalste@tm.net

>I ran the following through the calculator, but make no claims for accuracy.
>I have been known to transpose. <:-))

As have I. There was that major 19.24 vs 19.42 dB gaff I made a few days ago.
:-)

I did want to add to your calculations by mentioning that RF calculator
distances make some simplifying, generally conservative, assumptions. It
assumes the antenna is a point source and that the exposure is in the main beam
of the antenna. Even in the radiating near field, such a beam is often slightly
upward, with the actual exposure in areas below the antenna being less,
sometimes much less, than the calculator indicates.

> Good incentive for a taller tower.

A point easily made with the FCC's material in OET Bulletin 65, Supplement B.
:-)

> I didn't plug in anything for 220 and up,
> but the distances go up even more.

Actually, the limits for exposure are the same from 30 to 300 MHz. Above 300
MHz, the limits start to rise again.

Ralph,
There are three types of "db's" used in antenna work;
1. dbi, pertaining to an isotropic antenna comparison.
2. dbd, pertaining to a dipole comparison.
3. dbbc, pertaining to a beer can comparison.

There is one more type of "bd's", use primarily in
making CB antennas. It is;
4. dbtslc, pertaining to a 'turd size lumb of coal' comparison.

>From: pete4www@juno.com

>I am a new ham, so I don't know a heck of alot about dipoles...

Took me a while to learn more about them than the formula on my General test.
:-)

If an antenna is advertised as a "dipole," it would generally be fed in the center, though I have seen a few advertised "off-center-fed" dipoles. Dipoles come in a number of flavors, to the simple ones cut to resonance and fed with coax to simple ones not cut to resonance and fed with ladder line and tuned with a tuner (one antenna can be used on all HF bands easily that way) to various multiband designs such as trap, G5RV, fan, etc.

The ARRL has a nice page on dipole antennas at

http://www.arrl.org/tis/info/dipole-h.html.

Mike Gruber, now W1MG, wrote a nice article in QST that discusses various multiband dipoles. See http://www.arrl.org/tis/info/pdf/9611073.pdf.

Dipole antennas are generally intended to be used "flat," either horizontally or vertically. However, if you can only fit them by bending them around, you can usually get away with it. The effect of bending the radiating element would generally be to change the impedance and resonant frequency a bit. The resonance can usually be corrected by adding or removing a few inches or feet of wire. If the best SWR is higher than the frequency you want to operate, add wire; if it is lower than you want to operate, remove wire. Alternatively, you can use an antenna tuner to match the antenna system to your transmitter.

If the SWR on a coax-fed antenna is <1.5:1, you won't have to do anything to have an excellent match to your transmitter. If the SWR is >1.5:1, some transmitter's SWR protection circuitry might kick in, reducing transmit ppwer. If there is no SWR protection in your transmitter you can consider an SWR of 2:1 to be quite acceptable. If the SWR is < about 5:1, the coax will be reasonably low loss, but you will have to use an antenna tuner. You can often use a tuner for higher SWRs, but at higher SWRs, the losses on the coaxial feed line will start to be significant.

On an open-wire fed dipole, the SWR on the open-wire feed line can actually be very high, but the line loss is so low that the additional loss caused by SWR is usually not that important.

If you enjoy antennas, see the ARRL TIS web page at:

http://www.arrl.org/tis/#tech

and download the various reprinted QST and other articles. Last count, there are about 100 info pages and 500 articles there.

Source record: 181007

Hi, Jim:

If the wall is not metal, try two loops on opposite sides of the wall, ot two pieces of open-wire line. They will sorta-link-couple to each other -- you will need to experiment with size, etc. Rule-of-thumb: make the line spacing or loop diameter several times the wall thickness. Got this idea from the past, where someone got tired of using his continuous rotator as a line-stretcher/breaker <BG>.

I use a tuner and open wire line links to couple successfully 160-10M thru a sacrosanct brick wall to a 250-ft dipole. Glass, of course, is the simplest challenge.

>Chip, this is just plain wrong.

No it is not. Why do you require repitition on this?

If the dB scale is being used--as it usually is--to denote POWER RATIOS then one must do what one needs to get power UNITS, such as use Ohm's Law and square the values and incorprate resistance--hence the 20.

If the dB scale is being used as a logarithmic indicator of dynamic range of a quantity then one uses the dB SCALE to translate teh ratio into a number.

Accept the fact that there are many cases where dB is NOT used to indicate POWER.

Now Ed: your V/M measurements--so posed can NEVER give POWER. EVER. Unless you integrate over an area and DENOTE THE TWO AREAS USED IN THE COMPARISON then there is no way to get POWER. EVER.

I am extremely disappointed that some hands refuse to understand and use dimensional analysis in this context. dB is NOT a handy memorized set and forget plaything, but a wonderful scale with real physical basis and use.

>Roy Lewallen, W7EL
>

An order of magnitude voltage difference is a 10 dB voltage difference. It corresponds to a 20 dB difference in POWER. NOT voltage.

Either you lock into the definition of dB with respect to POWER ONLY or you don't.

In the first case, the comparison of 2 values on V/m can NEVER give power and thus you cannot give a dB value. In the second, for an order of magnitude difference, it is a 10 dB difference in V/m, and a 20 dB difference in power density.

There are not voltage dB and power dB; there are only dB.

>Either you lock into the definition of dB with respect to POWER ONLY or you
>don't.

Exactly, which is why dB = 10log(P1/P2) = 10log(E1^2/E2^2) or 20log(E1/E2).

>In the first case, the comparison of 2 values on V/m can NEVER give power and
>thus you cannot give a dB value.

If you square the values, the comparison of 2 values in V/m can give you a
power ratio, and for this you can give a dB value.

>In the second, for an order of magnitude

I've never tried it, but I do feel like I should be hitting my head against a
wall because it feels so good when i stop....:-)

You can never get POWER from a measurement of V/m. Other info is needed.

Just looking at the units tells you it is incompatible with that.

It's not clear why you've changed from talking about voltage to V/m.

The ratio of two voltages is given in any text, from beginner to college level, as 20 * log(V2/V1). Sometimes, as in the IEEE Dictionary definition, a condition is placed on the voltages that they be measured across the same resistance(*). An order of magnitude voltage ratio is clearly 20 dB. How you get 10 from 20 * log(10) escapes me.

Surely you have an ARRL Handbook, Reference Data for Radio Engineers, an IEEE Dictionary, Terman's Radio Engineering, or list of example questions for the Technician/General amateur license? If not, I'd be glad to fax you a copy of the equation from any of these (except the exam questions, which I don't have).

I won't bother continuing to correct you. Interested readers can look up the formula in a very wide variety of texts. You may have the last word -- the floor is yours.

Roy Lewallen, W7EL

(*)When they are, an N dB voltage change results in an N dB power change.

Why not?

I have a confession: if there is a winner I will pay this person within 24
hours of the deadline.

So far, no winners.

I will be happy to continue to give feedback on entries, at least for a few
more days.

Gene,
Use a neutral color, or a brown insulated wire for your antenna.
Wouldn't worry too much about high voltage and starting a fire in
the trees. Granted, there is high voltages present, but I've never
seen a tree burn from RF.

I need a copy of the manual for a Force 12 EF 320X240S I just picked up in a used tower, and got the Force 12 as part of the buy. Anyone who has this antenna care to zerox a copy of the manual for me? I will send a self addressed stamped envelope. I also would consider selling the antenna, if anyone is interested.

You wil heed some sort of insulators. How about this: go to a plastics supply company and get some green Lexan--the kind often used in welding screens. They may even have some scraps. Drill holes on the ends for feeding the wire thru. The Lexan will blend into the leaves. If you live in cold climate, you might try to go through cedars or spruce trees. Even small strips of 2 litre drink bottles will serve as temporary insulators.

Emulating Marconi who in 1901, about six miles from here used a kite (after his balloon blew away) to receivee the first transatlantic wireless message on Signal Hill St. John's, Newfoundland.

I seem to rember that wind pressure 'P' in pounds per square foot was/is;
P = [Velocity of wind (in mph), squared,] times 0.003 !
Thus;
At 10 mph. P = (10 X 10) X 0.003 = 0.3 lbs per sq.ft.
At 20 mph P = (20 X 20) X 0.003 = 1.2 lbs per
At 30 mph P = 2.7 lbs per ***
At 40 mph P = 4.8 lbs per
At 50 mph P = 7.5 lbs per
At 80 mph P = 19 lbs per
At 100 mph P = 30 lbs per .....
These are with surface perpendicular to the wind.
So don't try and hold onto a loose door or 4 by 8 sheet of plywood in a breeze!
So with a kite angled to the wind etc. you'd have to use what is it, the cosine or something?

So with a 'one square metre' kite, that's about 10 square feet roughly, in a 30 mph wind *** you could get well over 200 pounds, of 'pull', especially during a gust!

Don't get 'bowled over' by your idea! And, if you happen to let go of the string we'll be able to wave at it as it flies over Newfoundland, eastern Canada, on its way to North America! Oh, no hold on, the prevailing wind is usually the other way!

1868. FA: rhombic terminating resistor, large

Obviously we need require only demonstrated knowledge of the rules and
proper operating practices. The bar should be lowered as much as
possible to admit as many users as possible to the bands. If crowding
results, a large number of hams will likely get more band space.
Politics is like that!

The average ham should look a lot more like the face of America and not
like a bunch of freaky geezers.

With a big market for new technology in the ham bands, suppliers will
respond with the latest and greatest for hams to evaluate in the best
way, that is in the hands of demanding end users.

Best regards, Richard JHarrison, KB5WZI

1870. Crazy? Receiving antenna experiment

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-13 00:00:00 UTC
From: Terry Sanford <tsanford@roadrunner.nf.net>
Message-ID: <39C027FE.EF2C37E8@roadrunner.nf.net>
Source record: 180938

I have the possibilty that I could drape some 1000 feet and maybe up to 1000 metres of fine gauge (insulated or varnish covered ex transformer winding wire etc.) in some trees in a west east direction.
One end would be on our propeerty and the other across some rough woodlands. There would be no prblem getting permission from the other owners.
How straight I could do it is doubtful; also how high I could get it, maybe 10 feet? Also the land slopes from west to east, towards the coast, but is several kilometres from it. You get a clear view of the ocean horizon from our land.
Frankly the wire wuldn't last very long! Maybe a few weeks, in summer?
It would be possible to put a terminating resistor at the east end of the wire connected to some sort of ground rod.
Obviously what I'm thinking about is a 'rough and ready' Beverage, with its end towards Europe; the terminating resistor idea being to attenuate/absorb signals from t'other direction i.e. eastern North America.
Crazy idea maybe but comments anyone?
Purpose to receive European broadcasting and long wave stations, but also 160 etc.
Terry S. Torbay, east coast of Newfoundland, Canada.

1871. Re: Zen archery

Newsgroup: rec.radio.amateur.antenna

Message-ID: <39C02EA1.EBD8DB03@hiwaay.net>
Source record: 180939

This is the fractanal way of designing an antenna-

1. bend wire
2. measure frequency
3. say- "oops"
4. adjust wire length
5. go to step 1

Notice- this process makes one "loopy"

1872. SWR calculation needed.

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-13 00:00:00 UTC
From: Robert Fanfant <fanfant@ix.netcom.com>
Message-ID: <39c03943$1@news.microsoft.com>
Source record: 180940

Would appreciate getting the algorithm/equation to calculate SWR given separate forward and reverse voltages. Am in the process of writing the software for a homebrew microprocessor controlled auto-tuner. The coupler returns separate forward and reverse voltages in the 0 to 5V range depending on SWR. Plan to convert both voltages using an 8 bit, 8 channel A/D.

For those that have done this before, are there any suggestions for potential gotcha's????

Thanks in advance,

-rob N7QT

A good reference article for the design of mobile antennas is
"Short Antennas for Mobile Operation" by J. S. Belrose, VE3BLW,
who I assume is the same Belrose who has been delighting us
with antenna articles for years. It's on the QSTView CDROM and was published
in QST, September 1953, p30.

(I put the calculations into a spread sheet and soon will be winding lots of
turns to load up a 102" CB whip on 160M.)

The Belrose most familiar to amateurs and professionals alike is John (Jack) Belrose, VE2CV. Perhaps they're related; I know Jack has several children.

1876. 2m/70cm Base Antenna Comparisons

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-13 00:00:00 UTC
From: "J. Marcus Ziegler" <UseMyLastName@accesscom.com>
Message-ID: <ss0g8j8hct6180@corp.supernews.com>
Source record: 180944

Can anyone suggest a source of information comparing various 2m/70cm base station antennas from companies like Comet, Cushcraft and Diamond (and others)?
I live in a deep canyon and could use some more gain than my existing discone just to hit the local repeaters.

Antennas like the Cushcraft AR270/AR270B, Comet GP-3/GP-6/GP-9 and Diamond X-50A/X-200A/X-510MA.

I have looked at eHam and the ARRL manufacturers reviews and didn't find much information there.

Richard, is that a very small book with a red cover? Those words sound very familiar and I think I read them in a red book about 50 years ago.

> 'Doc

I haven't burnt one up, but I've gotten pretty close. But the branch I toasted was fairly green and had leaves on it. And was near the end of a dipole. It tended to look like I had held a lighter up to it for a while. Really fried, but hard to light as it was green. So I don't doubt its possible to start a fire, but seems to me a branch dry enough to do this would act as a pretty good insulator, so really shouldn't be a problem. I think it's damp green trees and water that will give you the most trouble. Or has been in my case anyway. Also the time I toasted the tree was with a good KW of power. Maybe a bit more. "1300-1400w". I since changed to insulated wire and have had no trouble at all. I've had many wires thru trees with no trouble at all. "I have 440 ft of wire thru trees at this time" It's only at the high voltage points that you will really have many problems. IE: the ends on dipoles. So if anything keep the ends insulated and you've got 85% of it licked. The house wire I use now seems to insulate quite well. But I imagine constant rubbing could wear it off after a while if the tree moves alot. Hasn't really been a problem here yet. MK

The little red book was fun to read. Instead of saying, we`re going to initiate an investigation of differentiation through the delta process, the author simply says, were going to take a little bit of x and a little bit of y and---. I remember thinking, now that`s the way to write instructions! I`d like to find and read that little book again.

Agreed, but the needed technical knowledge is minimal. There are many automobile drivers who hardly know the difference between a spark plug and a carburetor yet are safer drivers than some automotive experts behind the wheel.

> Jon M0BQQ

My very first field day, as a novice (a dumb one at best), I used what was called a kitoon. It was a 6 foot high T shaped baloon kite filled with helium. That held up 300 foot longwire for 24 hours, and was great fun for an unknowing novice. I would opt for a commercial baloon kite or dirigible kite as one sees at car lots, and that kind of thing for display. The main problem will be gas leakage, and the replacement of the gas. That can be expensive over a long term use. But, for a quick use like FD or some testing, it should do well.

Don't worry about it. Just get it up and run with it.
A few leaves can alter things a bit, but not enough on a simple antenna
to make a great difference. The insulation on the wire will usually
suffice unless you plan to run a kw, where more stringent requirements
would be better. The enamel coating on magnet wire is reasonably
tough and will last a season or so. It is cheap enough that you can
put a new one up every year. Use colored line that is mostly green or
grey if you can find it, and try to find cord that is braided rather
than twisted, since it rolls less in the tree limbs. I find that a
classic green 66 foot roll of bell wire makes a fine 160/80M antenna,
and, if you cut it for 90 or 45 feet, works fine on 40M too.
Just keep all antennas away from any power lines.

Good Luck....

I seem to recall you said something about preparation for an IPO by Fractal Antenna Systems,Inc. Rick. I can re-post if your memory needs refreshing. On what factual basis do you pose this information and why do you feel that it requires global, public dissemination?

In other words, what is your motivation and intent in such comments as: 'Dunn and Bradstreet' and ''pre-IPO"?

Would you agree, in any case, that inaccurate information poses grave threats to firms, no matter what the size or stage?

Would you further agree that, given several recent publicized convictions, that those who spread false information about firms on the internet, put themselves at severe risk for jail time and major fines?

With best Wishes,
Chip N1IR

Steve,

It's a big world and one thing I've learned about business is you better to
nice to people-- but watch your back.

I've also learned that some individuals will waste precious time at my costly expense. The best thing to do with those people is write them off. History. Life is short and there are billions of other people. Living is an important enterprise so don't waste it .

Accept the fact that I see no reason whatsoever to have anything to do with you.If asked to do so I will respectfully decline and recommend turning you over to someone else.

Please do not correspond with me in any form. If you cannot abide by my wishes then I will take your further statements as harassment, with legal consequences.

Nathan Cohen, Ph.D.

1901. Take the Pledge -- RE-POST!

RE-POST!

Hi, All concerned:

Some of us have organized a self-help group for replying-to-troll addicts. It is a slice of life from the NG, and its occasionally-disregarded motto, pledge, and mantra are identical:

DO NOT RESPOND TO TROLLS*.

Come and join us. It's among the hardest, most-rewarding accomplishments, sorta like a piled-higher-and-deeper from a poison-ivy league school. To join, simply comply with the pledge. We're as close as this NG, and we'd love to have you.

One of the beneficial side-effects of adherence to the Pledge is that of observing the increasing shrillness and irrelevance of the f-word trolls as they attract fewer responses.

I myself was pulled back from the abyss of responding just the other day by a fellow member, who reminded me that one response is too many, and a thousand not enough.

BTW, the private e-mail is deliciously funny. Several members have reported good success with the technique of creating a folder of laughing-and-finger-pointing posts they would have sent publicly before taking the Pledge. They are exchanging files with each other occasionally, and reported results are better than professionally-done comedy.

Fellow members: with apologies to the Brothers Grimm, could we adopt 'Billy Goats Gruff' as our group monicker?

73, Dave, K3BHJ

Hi I am looking to Buy a 10-80 meter Double Bazooka Dipole antenna...

And wanted to know any PROS or CONS on the antenna...

Will it hold an Amplifier 800Watts?

How does its rate with the Windom, or any other slopers

Thanks for your input...

Joe W1JAS Terryville, Connecticut.

N.L. Cohen We have converted all letters from you and will be placing on web for all world to see as you have asked.
We have now received translation of US patent office document and all at Institute have good laugh at your stupid description and wrong application of fractal wave theory, you still not abel to explain theory of fractal antenna how can you when your listen to Misha who not know full information and you physics knowledge is limited and not applicable to fractal wave antenna fields.
You must first learn CORRECT gravitational wave theory not the BS theory that you use and write about in Cornell Astrophysics 85 document which only apply to gravitatonal lens.
We now understand that patent office only give you utility patent, Office must have smart people working They know you still not understand fractal element antennas and correct mathematics.
We have people check your company and see that you transfer to home address from your father8217s location in Florida on 16/08/00 and that you are owner and president.
Institute has sent information to president of Boston University and our advocate in Moscow who will be talking to patent office about theft of Institute Intellectual information.

This is the same bull crap you put out on the 2 meter "Beta Test". Are there no hams in the world capable of testing your antenna!

We saw no results of your last beta test, or even if it was ever done. I think the whole thing is a fraud designed to mislead the ham population.

I will state with out equivocation, that based on your offers that it is my opinion that you, your company, and your associates are only using this as a ploy to advertise on the newsgroups.

I have forwarded to my legal representative the characteristics of my antenna range, my test equipment, and statements from other hams that have used my facility, the capabilities of said range.. It is my intention to file suit for fraud, naming both Dr. Nathan Cohen Ph.D. and Fractal Antenna Systems Inc.

Just ask:

SANTA BARBARA ANTENNA TRIALS - AUGUST 17, 1997

Here are the results from the 75 meter mobile antenna trials
held near Santa Barbara on August 17 1997. The callsigns and names
are self explainatory. The numbers, typically between 59.0 and 65.0 are
the measured field strength readings in dB. The field strength meter
measured
the horizontal magnetic field component of the radiated signal at a
distance
of approximatly 800 meters and accuratly represents the vertically
polarized
(electric field) groundwave, which is proportional to the low angle
skywave
radiation suitable for working DX. The measurements do not necessarily
reflect the performance of the antenna system for working short skip
(NVIS)
but are generally a useful indicator of overall performance. In most
cases, the measurements were done at 3995 kHz but we allowed the
frequency
to be lowered if required to achieve adequate power transfer. The power
input to the antenna system was taken as the difference between forward
and reflected power as measured with a Bird wattmeter anywhere the
operator could provide feedline access, usually at the rig antenna
connector.
The forward power was typically between 40 and 50 watts and all readings
have
been normalized. The absolute value of the field strength measurements
have
no meaning whatsoever but the differences accuratly reflect antenna
system
differences. Note, for 75 meter mobile installations, the vehicle is a
major
part of the antenna system and the data reflects entire antenna system
performance. In some cases, extensive bonding of body and frame members
has
been done to reduce losses and improve counterpoise effectiveness.

Unless
stated, all vehicles were legal to drive with in the state of California
with
the antenna systems deployed and presumably operable. When the field
strength
trial began at around 0800, there was a slight drizzle which tended to
detune (down frequency) the open air bugcatcher coils by around 20 kHz.
The
earlier measurements made with the bugcatchers tended to be a couple of
tenths of a dB below the later measurements and I believe that to be as
a
result of water on the coil and not a shift in antenna range
calibration. In
the past we have found the same equipment to be repeatable to within +-
0.15 dB
or better. The comparisons can be expected to be accurate to +- 0.2 dB.

RESULTS

CAPACITY HATS: These antennas had capacity hats of some sort for top
loading.

K7POF - BOB 64.8 (lST RUN) 65.1 (2ND RUN LATER IN THE DAY)
W6MMA - VERN 64.9
W6RCA - CECIL 64.9
N6BT - TOM 63.8 (lST RUN) 64.8 (2ND RUN) 66.0 REAR ASPECT
K6SDQ - JIM 63.2
KE6DM - BOB 63.0
K6MB - JAY 59.2

BUGCATCHER TYPE: Whip only, no top hat.

K7POF - BOB 63.2
WA6JPR - WALLY 62.3
WB6HQK - BART 61.7
K6MB - JAY 60.4
W6RCA - CECIL 58.3
W6JEO - CARL 57.7
W5GYJ - JIM 57.2
KC6MAJ - PETER 52.7
WB6ZJA - JIM 51.9
SCREWDRIVER TYPE: Various manufacturers

KE6ELQ - FRANK 64.3 DOES NOT MEET VEHICLE CODE - 20' TIP TO GROUND.
W6MMA - VERN 63.2
K6RCL - DENNIS 62.6
WA6HEY - JAKE 62.1
K7EZ - ROGER 61.9
KA6TAY - GREG 61.8

OTHER:
W6YY -SANFORD 66.7 DOES NOT MEET VEHICLE CODE - 30ft ANT, TOP OF

MOTORHOME
WA6JPR - WALLY 61.1 BANDHOPPER
WA6JPR - WALLY 59.5 BANDSPANNER
WA6JPR - WALLY 58.3 STAINLESS STEEL FORTEX COIL
KK5YY - GERALD 56.4 ROOFTOP MOUNTED OUTBACKER WITH TRIPLE MAGNET
MOUNT
W6RCA - CECIL 52.2 11.5' WHIP (NO COIL)

ADDITIONAL DETAILS:

CAPACITY HATS:

K7POF - CENTER-LOADED, LARGE CAPACITY HAT, WIRES TO FRONT.
W6MMA - BBS SCREWDRIVER, 5' HAT WITH 18 RADIALS, R. FRONT BUMPER.
W6RCA - HOMEBREW MID-BACK BUMPER, OVER THE VEHICLE,TOWARD FRONT. 4:1
UNUN
N6BT - FORCE TWELVE PLUMBER'S DELIGHT ALL AROUND VEHICLE.
K6SDQ - CENTER-LOADED WITH 42" HAT @ 11 ABOVE COIL. LEFT REAR.
KE6DM - CENTER-LOADED MID-BACK BUMPER 17" HAT.
K6MB - LEFT, REAR MOUNT, CENTER-LOADED WITH TWO WIRES TOWARD FRONT.

BUGCATCHER:

K7POF - MASTER MOBILE, LEFT REAR, 7011 BASE, 64" WHIP.
WA6JPR - BUGCATCHER, MID-BACK BUMPER MOUNT. (NO PAPERWORK)
WB6HQK - 5.25 INCH DIA COIL ON 2.5 FOOT MAST MOUNTED ON TONNEAU COVER,
72 WHIP
K6MB - BUGCATCHER, LEFT REAR.
W6RCA - TRAILER HITCH MOUNT, 3' BASE, 6X6" COIL, 5' TOP.
W6JEO - BASE-LOADED, 2x12" COIL, 62.511 TOP, 3.5' GND TO BASE.
W5GYJ - BASE-LOADED, 8x12" COIL, 7' TOP, 3' GND TO BASE. (GLA COIL)
KC6MAJ - CENTER-LOADED, ON TRUNK, 3X5" COIL. (HUSTLER COIL)
WB6ZJA - TEXAS B.C. LEFT ABAFT CAB MOUNT, 16"-HAT 12" ABOVE COIL.

SCREWDRIVER:

W6MMA - AS ABOVE SANS HAT.
K6RCL - HIGH SIERRA 1000, CNTR-LEFT MOUNT, GMC P.U.
WA6HEY - W6AAQ ANT., REAR, LEFT MOUNT @ 43" GND TO BASE.
K7EZ - W6AAG ANT., REAR MOUNT, 36" GND TO BASE.
KA6TAY - HIGH SIERRA, CNTR REAR BUMPER MOUNT 16" GND TO BASE.

OTHER:

WA6JPR - BANDHOPPER.
WA6JPR - BANDSPANNER.
WA6JPR - STAINLESS STEEL.
KK5YY - OUTBACKER,CNTR-ROOF, MAG-MOUNT.
W6RCA - 11.5' WHIP (NO COIL) TRAILER HITCH MOUNT.

Additional Notes:

KC6MAJ and WB6ZJA apparantly had grounding problems and the results are
not typical of similar installations.

These are the final results but updates may occur as additional
information
becomes available. If you have any additional information or errors to
report, please let me know.

If you have any questions please feel free to email me:

Very interesting coverage Roy that was educational
of itself

I have no business intruding in such a
complicated matter but wouldn't there be a large
area on the ground where the signal angle is a variable?
Or does it really" bounce" to an instant change in trajectory.
Somehow my gut tells me that as the frequency is lowered
more features come into play than in say 10 metres with
respect to wave travel contours. We all tend to extrapolate
beyond observed boundaries and maybe this is one of those cases
It also comes to mind the use of low frequencies
by the military in "unfreindly environments" such
as under water e.t.c.where temperature comes into the picture
which is not of consequence in HF. frequencies but comes also
into play with VHF
But as Sergeant Shultz would say
" I know nothing, nothing"
Regards
Art Unwin KB9MZ

Hi Joe,

A double bazooka is no different than any other dipole. There is a lot
of misleading hype about that antenna.

Save your money, and put up a regular dipole.

Another interesting point, how can one have a 10-80 meter bazooka? The
bazooka's claim to fame was that it was comprised of 1/2 wave length in coax
coupled to 1/2 wavelength in wire. Supposedly the impedance was corrected by
this setup to allow a wide bandwidth. I, like yourself, have never found
this to be true in practice.
But! a claim of 10-80 makes no sense what so ever.

On 75/80 I use a 12" diameter cage dipole. It is the best setup I have
found that is practical to install.

Joe, also the double bazooka is a single band antenna...no 10-80 coverage.

A dipole is open ended a Double Bazooka is DC grounded thru itself taking away a lot of noise. Also you have a LOT more bandwidth than a dipole so you wont need to use a tuner as often. I dont like the weight issue though. They are a lot heavier. I will stick to my double bazooka. I would make one versus buying one though.

Source record: 180889

CAM wrote:
> I will publish a summary of the results of all the shootouts
> that I know about.

Here's the promised summary based on three 75m shootouts.
These are relative average estimates without absolute accuracy.
(In fixed font)

Good Screwdriver or Bugcatcher with good top hat 0 dB
Good Screwdriver or Bugcatcher without top hat -2 dB
Base Loaded Whip, Bugcatcher coil -5 dB
Hustler -8 dB
Outbacker -9 dB
Hamstick -12 dB
138 inch whip with SGC-230 -13 dB

Assuming the 0 dB mobile antenna is radiating ten watts,
the 75m Hamstick would be radiating less than one watt using
the same transceiver.

The is a catch though. The wider bandwidth is due to loss in the coax. A regular wire dipole will have a slightly higher performance. MK

Unless I am missing something, the double bazooka is a mono band antenna-
at least when functioning as a broad band dipole. Even the benefits of the
broad VSWR response are somewhat in doubt as it appears the increased BW
is a result of loss in the coax matching sections. Any comments?

I'd be very careful with this one. The laws of physics say that if RF
energy is to radiate, it must flow through a conductor of some kind.
You can not just bottle it up at a single point and expect radiation.
It is possible that this device causes the RF to flow mainly through
the cable connecting it to the rig, or perhaps a separate ground wire
or some combination thereof. I wouldn't send any money until it has
been reviewed by several independent hams.

1927. Re: Best Wire for Buried Radials

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-14 00:00:00 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <8pr8ld$5eb$1@neptunium.btinternet.com>
Source record: 180719

Neglecting propagation effects, with un-insulated wire there is just a simple resistance between the wire and mother Earth.

When the wire is insulated there is a very slightly smaller resistance in series with a capacitance.

The capacitance is that between a pair of coaxial conductors. Inner conductor diameter is that of the wire. Outer conductor diameter is that over the insulation. The dielectric constant is that of the insulant. Pvc has a considerably greater dc than polyethylene.

The capacitance of 14 awg wire insulated with pvc of thickness = 1 wire diameter, is about 80 pF per foot or about 270 pF metre.

The capacitance per foot of enamel-insulated magnet wire is much greater. Forget it at HF.

So the equivalent input impedance of a set of buried, insulated, radials is that of a large capacitor in series with a resistance.

When a vertical antenna is mounted above such a radial system a bottom-end loading coil is needed to tune-out the capacitative reactance. In practice it just needs a few more turns on a loading coil, needed in any case, to resonate a short antenna. Or it disappears into the tuner and the operator is unaware of its existence.

Radial wires also have inductance which usually results in the input impedance of a buried un-insulated radial system having a +ve reactance. Unknown to the operator, the tuner then supplies an effective series capacitance to tune it out.

And the foregoing partly explains why operators having nominally identical antenna + ground radial systems have different degrees of success in getting then tuned up on all bands.

Hi Terry,

You're low longwire could be considered a Beverage antenna.

The information above is incorrect Terry. I have almost 30 Beverages
here, and they make fine receiving antennas. There is very little
difference in Beverage performance if you have belly in the spans.

Here are some general guidelines:

1.) Keep the antenna reasonably straight and pointed in the direction
you want to receive. A few degrees (say under fifteen degrees) of
pathg deviation won't hurt as long as the antenna is generally
centered on the direction you want to receive.

2.) At about 1-1/2 or 2 wavelengths, the directivity stops increasing.
That's because ground losses below the antenna sap energy from the
wire.

3.) Keep the Beverage low. The Beverage must be under about .02 WL
high or you will start to loose directivity.

At higher heights, the Beverage acts more like a long wire. You can
use longer lengths of wire effectively.

Like Doc, I think your wire is too small.

You may not care about any of this, and just want to reel out your
wire. Have fun.

If you are serious about receiving weak signals, I suggest you do a
Web search on Beverages or look at a copy of Low Band DXing by ON4UN.

Short spikes won't hack it on a redwood. The bark is fairly thick and
very soft. You need to penetrate that well or you're in for a very
unpleasant experience... Hi.

Wayne, a rear deck clamp on antenna mount and a ham stick for ten meters would do the trick. The antenna you describe sounds like many I see mounted on 18 wheel trucks. I think it is designed to be co-phased. By son, KB5EAG, uses a set on 11 meters from his 18 wheel truck (He is an owner operator.), but has had no trouble using a switch and two coax feeds. He switches between the two antennas to gain directivity.

The only reason for the shortened antenna is because if they were any taller - they would be too tall for the highway when mounted on the side mirrors of the big trucks.

Again, I recommend the trunk lid clamp on mounts. They work great on the rear door of a van and can handle a full sized mobile amateur whip.

http://www.x10.com/products/x10_vk45a.htm sells a 2.4 GHz camera and receiver for less then a $100 bucks. I have one in my office at http://www.olt.net/webcam/

The produce good color images and also include an audio channel.

Here is an excerpt from their web site.

XCam2 is a Tiny Wireless 2.4GHz Super Sharp COLOR Video Camera that lets you view ALL the action!

* Instant LIVE audio and video
* Works Right Out of the Box
* Sets Up in Minutes (hassle-free)
* Hands-free operation
* 2.4GHz transmitter (clear, sharp)

The setup includes both the wireless camera and the receiver. The receiver outputs RF and RCA feeds.

Thus providing some support for the notion that a formal education
decreases one's ability to think.

>
>-rob

Hi Rob,

This is exactly the logical problem that I describe as getting caught in a local minima. The problem is you have so much control, that you could easily(or difficultly) find several solutions. The common first step is set the caps fully meshed and the inductance at its least value. The common second step eludes me (aside from the obvious fumbling to lower SWR). This also says nothing of tuning up first into a dummy load - I will skip that as not part of the game plan. Successive steps would undoubtedly resolve to a finer solution. However this does not guarantee the best solution.

The kicker to this call for a flow chart is that the program, to find the best solution, has to perform either a look-ahead or a look-behind well beyond the current settings to determine if another solution is available (much less better). Programming software in this category is sometimes called self-modifying or possibly as genetic algorithms. In other words, not a path to follow for the weak of heart. Why? because such programming can lead to logical nightmares for implementation and unstable operation.

This returns us to the possibility that the first solution will be the practical solution, and I am sure there are those with more time at the tuner that can give you a more reliable sequence of control setting than my feeble attempt above.

Interesting question. Can you use an additional, larger, parabolic dish to provide higher gain and capture area - pointing your smaller dish into the larger dish, thus achieving some level of gain?

Just a thought.

That's why I drilled a 4'' hole as with a 4'' hole you can get your
hand down the pipe and pack it tightly with Rock wool (or Glass fibre
of rags)
I also have room for a fair few runs of coax
It did annoy the wife but they get over this sort of thing Eventually

WA6INF (now W7SK) used a slinky dipole in his house to serve as the slow speed CW net manager on 40 meters in Oklahoma in 1974. I haven't seen one since. But it struck me as an ideal indoor wire antenna. The tuning for multiple bands was done with wire and alligator clips to short out portions of the slinky dipole.

It's always interesting to see what conclusions are drawn from surveys. It seems to me there's more difference between preschoolers and scientists than formal education (although some scientists are definitely much more like preschoolers than others). I think there's as much evidence presented by this study which indicates that increasing one's height, weight, age, or distance between the ears decreases one's ability to think.

Put up a statue of a great horned owl on the antenna - that should keep them away. Another solution may be to hang strips of cloth from the antenna and tower - one Expedition did that.

Hope the suggestions help.

I have a couple of these. They work OK under indoor controlled light situations. Outside, where the contrast ratio may be extreme, they don't. The automatic iris range is quite limited. They do have a range of about 100 feet out of the box. The receivers are very susceptable to nearby microwave oven QRM. Given these limitations, the X10 equipment could be quite adequate for certain applications.

The only antenna that has ever worked well for me on 75 meters phone, while mobile, has been the Hustler with high power coil. I have compared it to an 75 meter Yasu mobile antenna system and a Ham Stick.

I believe the Texas Bug Catchers would work as well, but have never had the opportunity to try one.

The so called 'single' bazooka uses one shorted 1/4 wl stub in parallel with the feedpoint of the dipole as opposed to the 'double' bazooka which uses two. The two stubs in parallel are equivalent to a single stub of half the characteristic impedance and provide a nice symmetric mechanical arrangement. In addition to the reactance compensation effect of the stub, using large diameter coax for the radiator has the effect of increasing bandwidth. Unfortunately, typical coax cable isn't structurally very suitable for supporting itself over long horizontal spans.

I used single element delta loop, (easier to fit on the tower). If you feed it at the top or the bottom in the middle, you get horizontal polarization (or with quad top/bottom corner/side feed) and at low heights radiation straight up. If you feed Delat loop 1/4 wave from the top apex you get vertical polarization and low angle radiation. By moving the feed point + - from the ideal position and by adjusting the height and length of the horizontal side close to ground, you can find 50 ohm point and direct feed with coax. With vertical polarization, good ground or bunch of radials will greatly enhance the performance at low angles. It beats inverted Vee in performance.

Yuri, K3BU, PDH (pretty dumb ham)

ps
on this ham newsgroup there is no need for titles, corporate ladder places etc. We are all just PDH on the first name basis. (Except for one freak who flashes his "credentials" when people don't agree with his garbage.)

I recall going through the analysis some time ago and concluding that really good bandwidth compensation for a dipole would require a stub with Z0 on the order of 7 ohms or so. (I'm sure this would depend on the antenna's wire diameter.) If I remember correctly, the broadening effect of the double bazooka's stubs is pretty small because of their higher impedance. Making the wire diameter larger and introducing loss will of course further broadband the antenna, as you've mentioned, and this might be more of the double bazooka's trick than the stubs.

1954. Re: Incorrect Understanding of Fractal Antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-14 00:00:00 UTC
From: sideband <sideband@cac.net>
Message-ID: <nqp2ss88005gt0rblk0ob3ug6ac5i9j814@4ax.com>
Source record: 180746

Zowie! A well thought out, well constructive, informative NG message about Fractal antennae! Chip should take this example to heart.

Thank you very much, Richard. You have disseminated more useful information in this one message than Chip has managed to in the last month and a half.

From this, I gather that, were I to desire it, I could build a Fractal which would be broad banded enough to cover both 10 and 11 meters with a relatively safe SWR and a decent radiation pattern.

Some background. I'm currently a CB operator (Not a CB'er. I know how to use SideBand properly ::grin::). I have been a member of the X-Ray (The Trans-World Sidebander's) club, and was Davis County, Utah, controller for the club for over a year, before I had to move. I am currently studying my code, trying to overcome audio dyslexia so that I may gain my General Class license in one shot. HF is where I want to "live" I enjoy atmospheric propagation, or "shooting skip" immensely. I'd like to do it legally someday, if I could just get that darned code down.

When I do get my ticket, I'd like to build a small (so the landlord doesn't complain too much), single antenna that would cover both 10 and 11 meters, as I will still talk on the CB, with a CB, after getting my license. Licensing doesn't mean I have to give up my friends on the CB band, ya know. ::grin::

Larger antennae for the lower bands, (20, 40, 60, 80, etc) probably won't be possible at my current location, and I'd like to have the best "ears" and transmit I can get from the smallest antenna possible for my location, on my bands of choice.

So from what you've written here, I'm assuming that a fractal design ::might:: be one possible answer.

But is it do-able?

Thanks again for your reply.

:>
:>-SSB
:
:Hi OM,
:
:I found nothing offensive, curt, or glib about your reasonable
:questions. I encourage any correspondent to participate in similar
:manner.
:
:As for your assumption:
:>I gather from these data that the antennas tested were not constructed
:>for operation on any particular band.
:This is entirely correct.
:
:My method was to ignore every consideration EXCEPT for wire length, or
:antenna height. I held these constant for every variation of design
:so that I could compare designs across all the various fractal forms.
:As a consequence of this method, I let the characteristics speak for
:themselves. Those characteristics revealed an ordering, and that
:ordering reveals that the simpler geometrical characteristics strip
:away the aura of magic from fractal.
:
:There are no pluses there are no minuses, there is simply the
:reporting of results of the variations made. There is no implication
:of best, there is no implication of worst, such assessments are beyond
:the scope of my surveys and they would be an inappropriate presumption
:on my readers' and their needs. My intent is to remain neutral and
:anticipate nothing. (Yes, this can make for rather dry reading.)
:
:This is not to say my pages are bereft of opinion or taking a stance.
:such writing is found in the side pages where I review designs that
:fall outside of my surveys. My practical design, soon to be
:published, is also a side publication. I hope it will satisfy the
:needs of those who wish to delve into this topic with wire and

:needle-nose pliers; but it remains a sidebar to my investigations.
:
:Why do I characterize these as "side" issues? Because this is simply
:derivative work of discovery not work that reveals basics of design.
:I seek satisfaction in the latter path (which in fact makes this
:posting very ON TOPIC), but I acknowledge the need for practical and
:demonstrable designs so that our readers here can relate to real
:applications. However, this practical design being a sidebar, it runs
:the risk of not being a very good example of a fractal implementation.
:This may become evident to the readership after I publish.
:
:I am not promising fractal dogs, but neither am I promising fractal
:saints. I can promise it will not be a Fragile Antenna.
:
:To attend to your more specific question (a very good one):
:>I'm just wondering what the real
:>advantages of these antennae are, aside from the size, if one is only
:>interested in a particular band or set of bands?
:
:My interest is not with small fractals. They are largely one band
:focused as an optimization. The k2 and my review show how
:"advantages" are found (it also shows how the application of a fractal
:solution is a forced one and is not necessarily the best solution).
:
:I find large fractals much more interesting, and in regard to your
:question, there may be more advantage found there. Of course the
:penalty is that you have a very large, complex structure. On the plus
:side, you also have a High Z extremely wide band antenna (on the plus
:only if you can cope with the High Z tho') and it shows gains in
:excess of 0 dBi (compare to the k2 being almost 5 dB down from 0 - but
:this comparing apples to road-apples... some might dispute which is
:sweeter).
:
:returning to the first assumption:
:>I gather from these data that the antennas tested were not constructed
:>for operation on any particular band.
:I consider it within the provence of an amateur to be able to
:successfully scale a design to any particular frequency (it is in fact
:extremely easy using EZNEC), provided of course, if they had
:reasonable access to the EZNEC file. This last assumption (mine) has
:always been supported by myself for all those who desire the file or
:the data.
:
:Now this may all sound hi-handed, my writing style certainly lends
:itself to such a stigma. It does not mean I will repel you with "do
:it yourself" because I realize that those who CAN do it for themselves
:are asking not for an answer, but for reassurance. This is not
:unreasonable either.
:
:73's

:Richard Clark, KB7QHC
:
:p.s.
:I hope it will come as a pleasant surprise that you will need neither
:pliers nor torch to build my design. A simple tape measure (metric)
:will be enough, insulated guy lines, and perhaps several dozen
:tie-wraps.

I went through the same analysis a few years back and recall 10 to 12 ohms was optimum for the particular 75/80m installation I was contemplating. I eventually concluded that a much better approach was to simulate the stubs with a L/C tank circuit where L and C could be chosen freely. Using an LC tank also allows an additional impedance transformation either link coupling or using an adjustable feed tap on the tank. My recollection is that losses of the tank are significant but considerably lower than stubs made from RG-58 or RG-213 coax.

> If I remember correctly, the broadening effect
> of the double bazooka's stubs is pretty small because of their higher
> impedance.

Seems like the ideal charactistic impedance for the stubs is something like Zf^2 / Za where Zf is the geometric mean of the feedpoint resistance at the series and parallel resonant frequencies, typically 75 ohms, and Za is the characteristic impedance of the antenna considered as a lossy transmission line, typically 600 - 800 ohms.

> Making the wire diameter larger and introducing loss will of
> course further broadband the antenna, as you've mentioned, and this
> might be more of the double bazooka's trick than the stubs.

In fact, if the stubs are made from RG-58 cable, the increase in bandwidth due to the losses is greater than the reactance compensation. The increase in the bandwidth resulting from using a radiator the size of RG-58 instead of #12 AWG is significant but minor compared to the effects of reactance compensation.

All in all, it's an interesting antenna to analyze and understand but seldom makes sense in a practical situation. I opted for a multiband solution using open wire feed and a manual tuner located in the shack.

I think Chip is absolutely correct, at least in his own mind.
If you display the" ball" or" mass of wire" or anything that could
resemble' it', you may be violating the American secrecy laws that
can be invoked whenever this Nation is thought to be in peril.
By displaying any information about these unique' wire' arrangements,
you make it much easier for unfriendly nations such as Iraq
to leapfrog years of tests and huge expense to instantly get at
the 'cutting edge' of this extraordinary science.
On the other hand if you made this 'thing' yourself you may share
the image with anybody, including fellow Canadians, Chinese and the Iraq's
as one can assume that the 'secret" wasn't a 'secret' after all,
just much ado about nothing.

Regards
Art Unwin

>. . .

I concur with the advice about segment length.

I haven't done very much modeling with native NEC-2, but believe it can handle 10,000 segments, if properly compiled for that value, just as NEC-4 will. (The limitation is really due to internal use of numbers over 10,000 to represent patches. I imagine it would be fairly simple to modify for more.) Certainly the pro versions of EZNEC handle the same number of segments regardless of calculating engine. (EZNEC 3.0 is designed for 10,000, but I don't know of anyone yet who's run a model with many more than 7,000. Earlier DOS versions max out at around 3000 - 3500 due to memory limitations.)

There are several examples that could be massaged to fit that requirement. Be advised however, for that much coverage, we are talking about a BIG fractal.

Hi OM,

My choice of large fractal for your antenna above is the safe choice. However there are a number of risk choices you can make from the variety of small fractals. By risk I mean that some fractal designs offer closely paired resonances, and there is the possibility that they could be scaled to cover 11 & some of 10. I suggest that if you have EZNEC, that you can shoulder this risk by taking the EZNEC file and experimenting.

Be advised that the following page reference is rated PG.
It contains assumptions of a perfect world where every design is judged against its peer in the purity of math. Intrusions of reality can be disturbing, but if planned for can give you the edge in which design to choose.

By referencing my page:
http://www.qsl.net/~kb7qhc/antenna/fractal/Constant%20Height%20Comparisons.htm
you may note that the last entry called Koch Quadratic contains two (2) entries for the 10M band. The part of the page I refer to is the reporting of best gain figures which is in table form. We are not immediately concerned with the figures as we are the significance of there being two (2) entries. Un-documented is the fact these two entries are at two different frequencies where there is a resonance or relatively low SWR (suggesting it would be tunable). You may note from this page there are a number of opportunities offering themselves as risk choices.

OK - you can look at those numbers for each entry. You have your choice of an antenna that will give you 11 dBi in the DX angles, or you can choose the one that will give you 8 dBi over those same elevation angles (0 - 15 deg). You may enjoy the sensation of tension as you ponder your choice that I believe must descend to "how easy is to build this sucker?" Or the less cryptic "is it worth 3 dB?" Or more to the point "16 meters TALL?!"

Now as for your last question (if you've survived the shock of my last statement):
>But is it do-able?
Look for a separate posting announcing my work.

Richard:

Again, Thank you.

Yes, 16 meters is a bit tall for an antenna. at this site. I had gathered, and I must have been incorrect, that Fractals were small in comparison to the height of, say, a dipole for the same frequency range. When I do get on the air for real, I'm going to stay mostly between 27.355 and 29.6?? Yes... that's 2.3~ Mhz bandwidth. I'm aware that this can pose problems in antenna design, if I don't wish to use a tuner.

I prefer SSB as my mode of operation, as I've stated before, and I'm not 100% sure which frequencies on 10M are acceptable for SSB, and which are FM/AM/Other. Perhaps a bit more research on my part might help narrow down my choices.

I consider a "safe" swr to be anything around 2.5:1 or lower. Maybe a dipole set for the center of my desired transmit range would be the better choice, using a tuner where necessary at the ends? Or would a fractal design help me realize the idea of transmitting without a tuner?

I'm just insanely curious about this idea. If the doggone thing actually can meet these needs, then I'm game to try one out, provided it's something I can put up in a tree, or on the side of the apartment building.

If not, I guess I'll just bite the bullet and run a couple of vertical dipoles, one for 10 and one for 11, out in the tree.

Thanks again, for the information, and your time. I do realize you are busy with this project, and others, and that makes these drops of information all the more valuable to me.

73's and good DX.

:
:Hi OM,
:
:My choice of large fractal for your antenna above is the safe choice. However there are a
:number of risk choices you can make from the variety of small fractals. By risk I mean
:that some fractal designs offer closely paired resonances, and there is the possibility
:that they could be scaled to cover 11 & some of 10. I suggest that if you have EZNEC,
:that you can shoulder this risk by taking the EZNEC file and experimenting.

:
:Be advised that the following page reference is rated PG.
:It contains assumptions of a perfect world where every design is judged against its peer
:in the purity of math. Intrusions of reality can be disturbing, but if planned for can
:give you the edge in which design to choose.
:
:By referencing my page:
:http://www.qsl.net/~kb7qhc/antenna/fractal/Constant%20Height%20Comparisons.htm
:you may note that the last entry called Koch Quadratic contains two (2) entries for the
:10M band. The part of the page I refer to is the reporting of best gain figures which is
:in table form. We are not immediately concerned with the figures as we are the
:significance of there being two (2) entries. Un-documented is the fact these two entries
:are at two different frequencies where there is a resonance or relatively low SWR
:(suggesting it would be tunable). You may note from this page there are a number of
:opportunities offering themselves as risk choices.
:
:OK - you can look at those numbers for each entry. You have your choice of an antenna
:that will give you 11 dBi in the DX angles, or you can choose the one that will give you 8
:dBi over those same elevation angles (0 - 15 deg). You may enjoy the sensation of tension
:as you ponder your choice that I believe must descend to "how easy is to build this
:sucker?" Or the less cryptic "is it worth 3 dB?" Or more to the point "16 meters TALL?!"
:
:Now as for your last question (if you've survived the shock of my last statement):
:>But is it do-able?
:Look for a separate posting announcing my work.

Briefly, EZNEC, both DOS and Windows versions -- is limited to 500 segments. There are two varieties of EZNEC pro, EZNEC-M and EZNEC/4. These are identical except that EZNEC/4 allows use of NEC-4 as well as NEC-2 as its calculating engine. As I mentioned before, v. 3.0 of the EZNEC pro programs is designed to handle 10,000 segments but as far as I know has been tested only to about 7,000 so far. DOS EZNEC pro is limited to about 3000 - 3500 by memory requirements.

Full information on all versions of EZNEC is available at http://eznec.com. I'm glad to answer questions, but request that you take a look at the web site first if possible.

A number of years ago, Randy Rand, AA2U was inducted into QRP ARCI's QRP Hall of Fame. As I recall, he had worked over 300 countries while running QRP (as defined as 5 watts maximum output on CW, 10 watts PEP sideband). This was well before anyone in the amateur community had heard of fractal antennas, so I'm sure one wasn't among the antennas he used.

I'm afraid I'm not very impressed by how many countries a person on the East Coast running a kW can rack up, and it sounds like a number of other folks aren't either.

The bugcatcher will outdo the hustler. Usually by a pretty good amount.
But depends on how good/tall the bugcatcher is also. You have short
ones/tall ones. The tall ones with good coils/hats hard to beat. The
hustler 80m super resonator fairly lossy. MK

Greetings all,

I'm contemplating building a dual band vertical for 160 and 80 meter use. I thought I'd try the simple, compact design I found in a book co-written by William Orr and Stuart Cowan (W6SAI and W2LX). They recommend using at least four 1/4-wave radials and four shorter ones run in random directions.

I have an R7 that I use for 40-10 and am wondering how I could apply their design to my project antenna. That is, how can I get reasonable performance with my antenna using very short radials like my R7 does. (It really works well!!) Does anyone know how to build such a thing?

Many thanks in advance.

One's perception of body heat frequently has nothing to do with actual body temperature.

When you are getting sick, frequently you feel very chilled, even though your core temperature may be above normal. This is because the mechanism your body uses to increase its core temperature (have a fever), is repetitive muscle spasms (shivering), which are interpreted as chills.

There are also paradoxical reactions, such as feeling chilled (clammy) when suffering from heat prostration. I suspect a chilled reaction to RF exposure is related to this, but certainly don't know it for sure.

The standard construction technique for medium wave broadcast ground systems in the US uses #10 or #12 bare solid copper. In soil types found in virtually all parts of the US, this will last as long as you are likely to be a ham. The exception are some volcanic soils or other very acidic soils and very salty soils. And these are only a problem if the soil is moist most of the time.

A typical amateur installation might have 10 to 15 radials about 60 feet long which is under 1,000 feet of wire. You should be able to find bare #10 Cu at about $100/thousand at an electrical supply house.

Only two things:

1. Fires have been reported on various newsgroups in recent years. I
personally have never had one.

2. I have observed the voltage present at the ends of antennas by
(carefully) drawing an arc. At the 100 watt level, arcs of 1/4 to 1/2
inch are easily drawn. That is more than enough to start a fire in a
dry tree.

Bruce,
Insulated wire would usually last longer than uninsulated. The
'best' wire to use is what you have the most of, or, what is cheapest
to buy. Galvanized fence wire should be cheap and last as long as
any, I'd think. If your worried about lightning, forget anything
below about a size #4. That gets to be a bit expensive, unless your
talking commercial antenna ground systems. For the average 'ham'
ground, almost anything will work (insulated lasts longer).

The idea behind the bazooka (double or otherwise) dipole is that the shorted 1/4 wl stub provides reactance compensation to the basic 1/2 wl dipole radiating element.

For example, as the frequency is increased above resonance, the feedpoint impedance of the dipole becomes inductive. The impedance of the shorted stub is very high at resonance and becomes capacitive at frequencies above resonance. Connecting the stub in parallel with the radiator has negligible effect when both the radiator and stub are resonant. Above the resonant frequency, the capacitive stub is supposed to parallel resonate the inductive antenna.

A typical low dipole over ordinary ground for 75/80 meters may have a feedpoint impedance of 50 ohms at resonance. Adding the reactance compensation stub will create a parallel resonant condition at a single frequency above, and below the resonant frequency of the dipole. The parallel resonance will transform the resistive component of the feedpoint impedance upward to a value which is dependent on the characteristic impedance of the stub and the choice of parallel resonant frequency. A typical value for the transformed feedpoint impedance is 100 ohms at parallel resonance.

At HF, the losses in the stub are significant, and for practical purposes, proportional to the feedpoint voltage squared. The feedpoint voltage is minimum at the 1/2 wl resonant frequency of the dipole and increases as the frequency is increased or decreased. Therefore, the stub losses increase on either side of resonance.

1979. NEC4 Model of MI2 Fractal Loop

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-14 00:00:00 UTC
From: VE9SRB <srbest@worldnet.att.net>
Message-ID: <a26w5.14130$6f1.580436@bgtnsc05-news.ops.worldnet.att.net>
Source record: 180823

I now have the MI2 Fractal Loop modeled in NEC4. The geometry of the antenna was not too difficult to track down, it is available at www.fractenna.com and in a paper by Dr. Cohen entitled "Fractal Loops and the Small Loop Approximation" published in Comm Quart - Winter 1996. Given the method used to enter the wire point coordinates, I believe that the point coordinates are accurate within 0.0014 wavelengths. I will be pleased to e-mail a GIF picture of the antenna or the NEC file to anyone wanting to see it.

The antenna geometry consists of 100 wires, each having 3 segments for a total of 300 segments in the model.

Preliminary results calculate the first resonance to have a resistance of 27.9 ohms which is pretty consistent with the 26 ohm figure presented in the referenced paper. Note that Dr. Cohen used EZNEC and not NEC4 to calculate antenna performance. Note also that the wire diameter chosen in the model does impact the results slightly.

I am in the process of comparing performance of this antenna to a variety of non-fractal designs and will post results when available.

More to follow ....

73,
Steve, VE9SRB

Quoting the ARRL Antenna Book, "Notice, however, that the efficiency of
of the (Bazooka) antenna drops to about 80% at the 2:1 SWR points. This
amounts to a loss of approximately 1 dB. The broadbanding, in part, is
caused by the resistive losses in the coaxial resonator stubs, which
have a remarkably low Q (only 20)."

Hi Richard,

It sounds like Sylvanus' style. He loved to deflate pretense. Every problem of calculus was handled with is native simplicity rather than the academic fog of boastful phd's.

The cover is paper (it is a paper back only 30-some years old), but is a reprint from the 1912(?) edition. The book is quite thin for the topic and coverage with something like 150 pages. About the size of a paperback murder mystery.

I have volumes of calculus that span significantly more pages, and certainly go to greater depth - and yet none could teach with such simplicity.

Steve,
Thanks for performing this yeoman duty and providing this to the ham radio community with no strings attached.
I look forward to seeing the GIF and the NEC4 files as NEC4 is my preferred modeling tool at present, yes I am trying Roy's great Windows product and I am beginning to like it.

Again Thanks.
Looking forward for the comparison information as well.

Yes, and tree climbing spikes are of different length depending upon
the type of tree. For example spikes used on redwood trees are much
longer than those use when climbing fir trees.

Surge impedance can be determined fairly accurately by measuring the
input impedance of the line with the other end shorted and then open.

Zo = Sqrt(Zopen*Zshort)

I believe this is true for all types of lines and dielectrics and isn't
based on the simplification provided by assuming R/jwL approx= G/jwC.

Hi Steve,

At the bottom of my page:
http://www.qsl.net/kb7qhc/antenna/fractal/Constant%20Wire%20Comparisons.htm
you will find my attempts to reduce both the form of the fractal, its
iteration, and the wire consumed in its construction into a formula
for determining the resonance of the antenna. I call it a "special
formula" in that it lacks the generality to provide coverage for all
iterations for any particular form.

Many who approach fractals are typically overwhelmed by the artistic representations of graphic artists. My first assumption was that perhaps there was some magical quality worth discovering in the ultimate fractal form. My studies reveal that the correlation between the fractal form and resonance is more pedestrian, relating to simple and obvious geometrical considerations. This, of course, simply restates what you observe above.

I illustrate this at the same page in the table of comparisons that lie just above the formulas offered. Here I order the various fractal forms and illustrate correlations between my orderings and their performance in relation to resonance. This may be observed in the column appropriately named "ordering factor."

This table is a reduction of the work of the surveys which in turn were the reduction of some several hundred pages of data. All data is, of course, freely available for inspection and for those pages that have yet to include the EZNEC file, any correspondent may approach me for copies or encourage me to make them accessible on my page.

For the general readership,

My work on providing a practical constructible fractal antenna, as promised for last weekend, has slipped given the bulk of correspondence I've gotten in relation to these topics. I will make every attempt to at least publish the work in progress (the construction details are nearly finished).

>Martin K7MEM

Hi Martin, Robert, Roy,

The problem may even go beyond the warnings you provide above. Tuning, through mechanistic or automated means, can fall into local minimas through a too narrow focus on parameters while missing the better match.

That is, the naive program may be satisfied with the settings of several matching elements at a 1.5:1 figure (a local minima) when another solution offers 1.1:1 (the best minima), but is not programmatically sought.

The difference between the two may be discarded for efficiency's sake (time to tune that is), and this issue of being captured in a local minima could easily be rationalized as a non-problem. But again, it is only an issue of software. And software is free isn't it?

As of this month, ALL FCC licensees are required to be in compliance
with the FCC RF exposure standard (which by and large is the same as the
ANSI standard of 1992).

I have never found a cellular phone site, wireless network, or STL that
was out of compliance with the standard (or within several orders of
magnitude of being out of compliance), and part of my practice is
concerned with determining such things. On rare occasions I have seen
point to point microwave or satellite up-links that fail to meet the standard.

In the past there were quite a number of FM and TV installations that
were ot of compliance, but most have been brought into compliance either
by making changes in the transmission system or by limiting the
possibility of human exposure.

RF heat sealing equipment has also been an exposure problem in the past,
but is rapidly improving as older machines are replaced. Since these
aren't licensed by the FCC, the FCC guidelines do not apply, but other
regulatory agencies have guidelines which are quite similar.

1996. Single element quad antenna - anyone using one?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-14 00:00:00 UTC
From: "Terrence R. Redding, Ph.D." <terry@oltraining.com>
Message-ID: <39C109D9.787DEAAB@oltraining.com>
Source record: 180840

I am considering building a single element quad antenna. The plane is to hang it like an inverted vee from the yard arm off the side of the tower and feed it with a 1:1 balun at the apex of the high point.

I am guessing that it will out perform my current inverted vee, have a strong horizontal component of radiation, and be a fairly quiet antenna to listen on.

I wonder, has anyone on in the newsgroup put up a single element quad and compared it to an inverted vee?

All responses appreciated.

Terry

1998. Re: Better hide your antennas!

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-14 00:00:00 UTC
From: Gray Frierson Haertig <gfh@haertig.com>
Message-ID: <39C10D2C.4FCC9BEB@haertig.com>
Source record: 180842

Shocks and burns are certainly a hazard around antennas - even without direct connection to the antenna.

This is seen quite often in LF and MF broadcast facilities. Picking up a 10' piece of rebar can produce a serious burn a few feet from a 20 KW AM radiator. In fact, compliance with contact current standards is much more of a problem than compliance with exposure standards at these frequencies. Burns and shocks around VHF and UHF antennas tend to occur less often because generally these antennas are several wavelengths away and people are not in the near field.

In the past, tower climbers have received shocks from tower members and hardware in the vicinity of operating FM and TV antennas. They have also reported breaking into a sweat when a nearby antenna was energized. There are also reports of skin burns (similar to sun burn) when riggers are in the main beam of operational microwave systems. There have been several people that have suffered severe health effects when grossly overexposed RF radiation. These include skin burns, hair loss, loss of salivary gland activity, and cataracts.

The source of the FCC exposure standards ultimately derives from thermal effects on the body. In a rather gross simplification of the actual process, laboratory animals were exposed to increasing levels of RF radiation until a change in behavior was noted. Using simulated tissue models, the Specific Absorption Rate (watts of energy absorbed per gram of tissue) was determined. The basic standard was set at one thousandth of this level.

The variations with frequency and some of the other parameters used in determining compliance are based on how well the body acts as an antenna and hence how well it absorbs energy from the ambient field.

You said there is NO possibility of using insulators.
Therefore, put the antenna up with no insulators - or
don't put the antenna up at all.

You do not NEED insulators. Just like I don't NEED
a tower. Sure I'd like to have one, sure it would enable
me to use a nice beam, sure it would give me a better
signal etc. Sure, it would be better if you could put
up a bunch of properly designed, properly insulated
etc etc dipoles - but go with what you've got and ignore
the posters who choose to ignore what you said and insist
that you use insulators. I've used all kinds of antennas
in trees, both with and without insulators. They all work -
some work better than others, but I have noted no
evidence that my uninsulated, bare wire, "tree mounted"
antennas have performed any better/worse than insulated
"tree mounted" antennas.

Richard:

Thanks for this information, which Chip has been unwilling to publish.

I gather from these data that the antennas tested were not constructed
for operation on any particular band. (I may be wrong on this.)
Assuming I'm incorrect in this assumption, is it possible to construct
an antenna such as these for optimal use on a particular band,
sacrificing other bands' performance?

I guess what I'm asking is this: What is the benefit of constructing
such an antenna if you're only interested in certain bands, other than
wearing out a pair of needlenose pliers and using all the butane in
your soldering iron?

I'm not trying to be glib or curt, I'm just wondering what the real
advantages of these antennae are, aside from the size, if one is only
interested in a particular band or set of bands?

>
> I believe this is true for all types of lines and dielectrics and isn't
> based on the simplification provided by assuming R/jwL approx= G/jwC.

My previous post was based on the assumption that Zo was not
necessarily constant throughout the length of the transmission line or
independent of frequency.

In the case of constant Zo:

Zoc = Zo * coth(gamma * x) and
Zsc = Zo * tanh(gamma * x) where

Zoc is the input impedance to the transmission line in ohms with the
far end open
Zsc is the input impedance to the transmission line in ohms with the
far end shorted
Zo is the characteristic impedance (complex) of the transmission line
at the test frequency in ohms
gamma = alpha + j beta is the propagation constant (per meter)
x is the transmission line length in meters

Since coth(gamma * x) * tanh(gamma * x) = 1, Zo = sqrt(Zoc * Zsc)
independent of gamma or x as long as Zo is constant.

At low frequencies where R/jwL >> G/jwC, Zo varies significantly with
frequency.

I am no expert, but the Nat. Elec. Code spells out the particulars.

Anyway, for consideration, what is the electrical voltage breakdown of
the average insulated wire we would be likely to use as radials (1kv),
and what effect would that be to a lightning strike.....(none).
Basically a not to worry situation. Lightning potentials would consider
the wire insulation a non-entity, for all practical purposes. Even the
HV RF at the end of the radials would consider it a non-entity at any
power of more than 100 watts or so.

If you follow the history of this thread, you can get back to the reports that his verticals, with an excellent radial system over what he believes would be poor ground, seem to perform a bit better than his dipole at >300 feet above ground, on 1.8 MHz.

If you can get a horizontally polarized antenna up about a half-wave, it will be a pretty decent DX antenna. But don't discount that vertical, especially if you are over a good ground (pastoral farmland, for example). And the bottom line is that, for some, they simply don't have the real estate or height to put up an effective antenna, so going vertical and improving the ground connection as much as possible may be the only practical alternative. For DX, I would definately choose a vertical, even with a poor ground, over a low horizontal antenna for DX. On the lower bands, ie 80M, a low horizontal antenna will be better for communications of a few hundred miles most of the time.

>discone just to hit the local repeaters.

You may need an antenna with a higher angle of radiation to get out of the canyon, like maybe a 1/4 wave ground plane.

The gain of a Yagi might also be helpful. May have to point it up toward the top of the canyon.

Makes sense to me. Redwood is very soft. Douglas fir, which I understand isn't really a true fir, is much harder and more dense. I don't know about true firs like Grand or White fir, but I'd be pretty sure they're harder than redwood, too.

Steve- your statement is certainly more concise. The point that is not made in any fractal write-up, is, that for any given iteration level of any given fractal form, the process parallels the recent "Zen Archery" series- you have to make one- then measure it, then adjust it.
(By "make" , I will cocede that the modellers, such as EZNEC, are a pretty good substitute, up to a point)

The purpose of radials isn't to connect to the ground. The purpose is to lower the resistance of the path which currents take on their way to and from the antenna. You can actually improve the efficiency of the antenna (that is, lower the resistance of the path) by elevating the radials above the ground, in which case there's no contact at all between the wires and the ground. With an elevated system, the incoming or outgoing field interacts directly with the radial wires. The insulation is transparent to the fields, so it doesn't make any difference (except for a slight lengthening effect). This direct interaction also occurs when the radials are on or under the ground. The coupling to the currents in the ground itself is primarily inductive and capacitive, rather than conductive and due to direct contact. This coupling is just as effective if the wires are insulated as if they're not.

You should take a look at NEC (National Electrical Code). A rebar ground
of at least 20 feet is the PREFERRED method of grounding a service
entrance, and REQUIRED on new construction where applicable.

This type of ground is usually called a Ufer ground. It might not be
applicable on some tower foundations because of a limited ground contact
area, but properly designed will have a much lower resistance than a
ground rod ground. There should be a good contact between the tower
base and the rebar cage, and it helps if the rebar cage is well tied together.

Richard,
Sorry to read that the bulk has swamped you, I do understand
that it only you at the keyboard and that you do not have a multitude
of staff to handle the correspondence.
I am glad to see that you are back on track for publishing the work in
progress, it is awaited with baited breath.
I concur that it is high time that a practical constructible
fractal antenna be put forth to the ham radio community for
verification of applicability to the hobby.

I can almost taste the snow coming in the air and I do not want to
run into conflicting results as a result of snowflake contamination.

Glad to see that you are back on track.

He uses EZNEC/4, which includes an NEC-4 calculating engine. (It can also be used with an external NEC-4 calculating engine, although to my knowledge no EZNEC/4 users are doing this.) I have seen no case where EZNEC/4 gives a different result than other formulations of NEC-4, and would be extremely interested if one is ever discovered.

But I'd be very surprised to find any significant difference between NEC-2 and NEC-4 results in modeling any fractal antenna. If anyone observes a difference, I'd really appreciate your letting me know, and sending me the NEC or EZNEC file. If a difference is seen, it's likely that NEC-2 is being pushed to the edge of its ability in some respect. NEC-4 holds in for a little longer at the fringes. (For example, NEC-4 will handle loops which are a bit smaller before giving bogus answers.)

2019. Re: NEC4 Model of MI2 Fractal Loop

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-14 00:00:00 UTC
From: VE9SRB <srbest@worldnet.att.net>
Message-ID: <uY8w5.14552$6f1.589772@bgtnsc05-news.ops.worldnet.att.net>
Source record: 180863

Just some preliminary results on my NEC4 MI2 Fractal Loop as compared to the work presented by Dr. Cohen:. This is presented to validate the NEC4 model

NEC4 Model Dr.
Cohen's Papers

Resonant Impedance: 27.9 ohms 25 - 26 ohms

2:1 SWR Bandwidth 1.15% 2%
wrt 50 ohms

Directivity: 2.18 dBi 2
dBi

Note that radiation efficiency is not presented because it is simply a function of the ohmic losses in the wire. In all cases, the efficiency will be the ratio of radiation resistance to total feedpoint resistance.

The slight differences between the NEC4 calculated values and those presented in Dr. Cohen's papers are not significant in the comparisons to be presented since I will be comparing different wire geometries under the same conditions.

More to follow ...

Hi Roy, Martin, Richard,

I've implemented a Pi network with the Caps & Ind driven by stepper motors. This design includes a phase detector and band switch detection. Problem is that I'm not quite sure what to do with the phase detector :-).

For example if the phase detector tells me that I need more C, what do I do, decrease L or increase C? If I increase C, which of the 2 caps do I increase ? Etc...

The software will remember the absolute locations for a 1:1 match by band, so when band switches occur, the software will automatically position the Caps & Ind to the last tuned postion for that band, then start tuning at that position for minimum SWR.

What would really be nice is if someone has a flow chart (i.e. steps) for tuning a Pi network given the SWR and phase (i.e. whose output state is to either Increase/decrease L or C, OR its a perfect match).

Hi OM,

I found nothing offensive, curt, or glib about your reasonable
questions. I encourage any correspondent to participate in similar
manner.

As for your assumption:
>I gather from these data that the antennas tested were not constructed
>for operation on any particular band.
This is entirely correct.

My method was to ignore every consideration EXCEPT for wire length, or
antenna height. I held these constant for every variation of design
so that I could compare designs across all the various fractal forms.
As a consequence of this method, I let the characteristics speak for
themselves. Those characteristics revealed an ordering, and that
ordering reveals that the simpler geometrical characteristics strip
away the aura of magic from fractal.

There are no pluses there are no minuses, there is simply the
reporting of results of the variations made. There is no implication
of best, there is no implication of worst, such assessments are beyond
the scope of my surveys and they would be an inappropriate presumption

on my readers' and their needs. My intent is to remain neutral and anticipate nothing. (Yes, this can make for rather dry reading.)

This is not to say my pages are bereft of opinion or taking a stance. such writing is found in the side pages where I review designs that fall outside of my surveys. My practical design, soon to be published, is also a side publication. I hope it will satisfy the needs of those who wish to delve into this topic with wire and needle-nose pliers; but it remains a sidebar to my investigations.

Why do I characterize these as "side" issues? Because this is simply derivative work of discovery not work that reveals basics of design. I seek satisfaction in the latter path (which in fact makes this posting very ON TOPIC), but I acknowledge the need for practical and demonstrable designs so that our readers here can relate to real applications. However, this practical design being a sidebar, it runs the risk of not being a very good example of a fractal implementation. This may become evident to the readership after I publish.

I am not promising fractal dogs, but neither am I promising fractal saints. I can promise it will not be a Fragile Antenna.

To attend to your more specific question (a very good one):
>I'm just wondering what the real
>advantages of these antennae are, aside from the size, if one is only
>interested in a particular band or set of bands?

My interest is not with small fractals. They are largely one band focused as an optimization. The k2 and my review show how "advantages" are found (it also shows how the application of a fractal solution is a forced one and is not necessarily the best solution).

I find large fractals much more interesting, and in regard to your question, there may be more advantage found there. Of course the penalty is that you have a very large, complex structure. On the plus side, you also have a High Z extremely wide band antenna (on the plus only if you can cope with the High Z tho') and it shows gains in excess of 0 dBi (compare to the k2 being almost 5 dB down from 0 - but this comparing apples to road-apples... some might dispute which is sweeter).

returning to the first assumption:
>I gather from these data that the antennas tested were not constructed
>for operation on any particular band.
I consider it within the provence of an amateur to be able to successfully scale a design to any particular frequency (it is in fact extremely easy using EZNEC), provided of course, if they had reasonable access to the EZNEC file. This last assumption (mine) has always been supported by myself for all those who desire the file or the data.

Now this may all sound hi-handed, my writing style certainly lends itself to such a stigma. It does not mean I will repel you with "do

it yourself" because I realize that those who CAN do it for themselves are asking not for an answer, but for reassurance. This is not unreasonable either.

73's
Richard Clark, KB7QHC

p.s.
I hope it will come as a pleasant surprise that you will need neither pliers nor torch to build my design. A simple tape measure (metric) will be enough, insulated guy lines, and perhaps several dozen tie-wraps.

Hi Gray,

This is true as far as it goes. There is further to go. RF over
exposure can also be experienced as a chill! This may seem
counter-intuitive, but the damage is there nonetheless.

Joe & Bonita,
I seriously doubt if your going to find an 'all-band'
double-bazooka antenna. They are made for a particular,
single band. Adding additional 'legs' for other bands
is going to create a ~very~ heavy antenna (if it'll work
at all).
What people forget, or don't know to start with, is that
while the SWR may be uniformly low across almost a whole
band, the efficiency of the antenna drops off as you get
further away from the center frequency. The SWR may still
be low at the band edge, but the antenna is much less efficient.
It sort of 'evens out', good SWR, but less output.

>
>Does anyone doubt this?
>
>Bill
>

I'm sure that there is no relation between the juiciness of an apple in August and the resonant frequency of a fractal antenna.

Antennas can be viewed as RLC circuits. Like all circuits, there are --or can be-- regions in the frequency spectrum where the the reactance goes to zero. Hence resonance is attained.

For fractal antennas, the L and C are very much determined by the geometrical shape of the antenna in a given form factor. Thus a given frequency or resonance is degenerate: it can be attained by several different fractal shapes and iterations in this context. For a particular resonance.

Hence to talk about the length of the wire and the resonant frequency is to indicate a profound absence of understanding as to what L and C are; what factors determine them; and so on.

There is no question that finding the equivalent circuit of a fractal antenna is a very difficult problem. That's not what Mr. Aycock is referring to, however.

Unfortunately Mr. Aycock has been banned from the below link, for re-posting a list- only offer(to provide a patent reprint) to a global, unrestricted USENET forum.

But others are welcome to the list:

fractalantenna-subscribe@egroups.com

is the place where such discussions may be fruitfully continued.

You certainly can make a beverage. however, you'll need to keep the antenna as straight as you can for best f/b . An inch or two droop isn't a problem for a beverage, say, 10 feet off the ground. But a 3 or 4 foot droop is. Also, the performance will very much depend on the uniformity of the ground.

Hi:

There was an article in QST a while ago abt exactly this topic. The kite design was a "Scott Sled Kite" which is reputed to have the ability to fly at high angles and in light winds.

Here is a URL that I found with pictures of the design. I'm sure that you could scale them up to whatever size you needed for the job. A few minutes prowling the net will turn up a lot more pages I'm sure.

The article used a kite about 8 feet across if memory serves me correctly.

Well, Roy gave you the formula:

>Roy Lewallen wrote:
>>
>> SWR = (Vf + Vr) / (Vf - Vr)
>>

however, it's not going to be that simple. Just having
the forward and reverse voltages is not enough information
to intellegently control a transmission line tuner. Without
phase information you won't be able to tell if you need
more/less C or L. If your program was going to be strictly
an itterative operation it could be done with minumum
information, but it wouldn't be very elegant.

What you are doing sounds like a fun project, however, I
think you need to grab a book on transmission lines and
antennas and give it a good read. Get a copy of the ARRL
Antenna Handbook. It has a lot of good chapters on transmission
lines, tuners, and antennas. It will give you a lot of insight
into your development.

Good luck on you project.

Bill:

I just thought I would add a more correct generalization to one of the statements made in this post:

"Fractenna" <fractenna@aol.com> wrote in message news:20000914070530.09407.00000300@ng-ff1.aol.com...

> shape of the antenna in a given form factor. Thus a given frequency or
> resonance is degenerate: it can be attained by several different fractal shapes
> and iterations in this context. For a particular resonance.
>

In my opinion, this statement would read more correctly if it were written more generally as follows:

For all antennas, the L and C are a function of the geometrical shape of the antenna within a given form factor. A given resonant frequency or resonance can be attained by many different fractal or non-fractal shapes with this form factor. Additionally, the length of wire used to create any given shape is critical in determining the resonant frequency or resonance of the structure.

That does not reduce the noise. The noise is at the operating frequency, not at DC.

Bazookas are no less sensitive to noise than any other antenna the same size and location would be.

Only sometimes. I guess you never listened to the 80 meter phone band back in the AM days. For the most part, it was just wall-to-wall heterodynes; only a few very powerful or very close stations made it. The rest was a dead loss. The size of the 80 meter band didn't change a bit.

>

The political truth of things is that as more and more persons demand easier and easier tests, the politicians will respond with easier and easier tests. Eventually, the end result will be no tests at all. I think that's the was it is with CB. If a radio "service" can essentially self-destruct when limited to only 4 watts of output, imagine what could happen to a radio service permitted to operate with more than a kilowatt!

lf you had a direct lightning strike, we're talking about MEGAvolts, and MEGA amps, both at the same time! This will kill any electrial equipment: period, if it dosen't set your house on fire.

On a lower level, the high electric fields stand a good chance of doing your computer gear serious damage. Unpluggging it all, including from the telephone line, will minimise the risk.

If your backup systems involve car batteries, as do most, I commend you for your providence! And I assure you, that If you have a lightning strike of sufficient vigour to explode a lead-acid battery, that will be the least of your problems!

Chip, N1IR wrote:
"Anyway, I think Terry should try your suggestion and then compare with the antenna up in the air."

The U.S. War Department had this to say in 1945: On-Ground Antennas
Insulated wires of sufficient length laid on the ground, or better on vegetation just above the ground, will provide ground wave transmission with vertical polarization in line with the direction of the wire, that is, off either end of the wire, and for moderate horizontal angles from this direction. Such low antennas have the advantage of being easily concealed. A length of 600 / F feet (where F is the operating frequency in megacycles) ((this was 1945, the big hertz wasn`t in vogue)), or somewhat longer,is suitable, if length is adjusted by trial to permit good transmitter loading. A 100-foot on-ground antenna attached to Radio Set SCR-536 (handie-talkie) gives at least as good transmission in such directions as the whip supplied with the set (this was a good-sized antenna, no rubber duckie), and can be more easily concealed. Half-wave on-ground antennas (see par. 661d for length) can sometimes be used for short-distance sky-wave communications."
Full-wave Horizontal Wire An unterminated
end-fed horizontal wire one wavelength long and a few feet off the ground will produce a VERTICALLY polarized ground wave, in line with the wire, which has a materially higher intensity than that from a short whip. This assumes that the wire is fed as described for end-fed half-wave horizontal antennas (par. 663). The horizontal radiation pattern is like a figure 8, the two maxima being in the forward and backward directions of the wire, with the field at 30 degrees from these directions only slightly reduced. This antenna can be used satisfactorily over ground of high or average resistivity, but not over sea water or salt marsh.

Best regards, Richard Harrison, KB5WZI

Hmmm ... funny you should mention the latter. I gave up on DX when all I could get out of anybody was "QTH is ... Rig is ... etc.". I gave up on passing 13wpm when they changed the test to the same "typical" QSO. Why bother if the only info that's going to be exchanged is a "standard" QSO? Jeeze, I can program my computer to do that while I play FreeCell. In fact, some do! Sad ...

Source record: 180673

Cecil, just to cover the remote possibility of you really wanting to know whether radiation resistance is involved with the input impedance of a buried radial wire, the answer is a teeny little yes.

But in the present context we are concerned with the resistance of the soil which shunts current away from the wire at right angles, whereas radiation is usually assumed to be represented longitudinally by a resistance in series with the wire. It effectively increases conductor resistance.

But as the field set up by a radial wire is rapidly attenuated with distance from the wire, 30dB per wavelength ?, only the near field exists. Radiation is so small it can be forgotten about in ordinary soils.

But with loose, exceedingly dry sand dunes, no rain for 10 years such as found in the Sahara, a single buried wire would radiate quite well when using a vertical 1/4-wave as a counterpoise.

But in Sahara conditions one could just use a 1/2-wave dipole laid on the sand surface. The HF skin depth of dry sand is so great the effective height of a surface dipole is quite high. Even Hateley's thing works after a fashion it seems.

Fancy an expedition to Timbuckto?

2055. Re: NEC4 Model of MI2 Fractal Loop (Validation of Model)

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-15 00:00:00 UTC
From: VE9SRB <srbest@worldnet.att.net>
Message-ID: <q%qw5.106$Cq6.5088@bgtnsc04-news.ops.worldnet.att.net>
Source record: 180674

In an earlier post to the NG there were several issues raised as to the credibility and/or validity of using NEC4 to model the MI2 Fractal Loop. Here is the validation of the NEC4 model I created.

First, looking at Dr. Cohen's paper titled: "Fractal Loops and the Small Loop Approximation" Comm Quart Winter 1996, he presents an image of the MI2 Loop in Figure 1. This image appears to be an EZNEC picture of the geometry with wire segmentation depicted. It appears that Dr. Cohen uses 3 segments/wire in some places and 4 segments/wire in others. In my first NEC4 model of the MI2 Loop I used 3 segments/wire throughout the antenna. In a newly revised model, I am now using 5 segments/wire to mitigate concerns regarding segmentation issues.

As for the NEC4 results, here is a comparison of my NEC4 calculations and the results presented in Dr. Cohen's paper. Dr. Cohen's results are presented in Table 1 of his paper

Dr. Cohen
NEC4

First Resonant Resistance 26 ohms 28.4
ohms
Gain (see note below) 2 dBi
2.14 dBi

Third Resonant Resistance 18 ohms 19.0
ohms
Gain (see note below) 4 dBi 4
dBi

Frequency Ratio 1st and 3rd Resonance 1.79 1.82

Note: Dr. Cohen uses EZNEC to calculate gain based on ohmic losses in the wire. NEC4 presents directivity information. This is not a significant issue since the two antennas I will be comparing have identical wire length and identical wire diameter.

The model of the random geometry configuration is complete. Results will be summarized shortly.

73,
Steve VE9SRB

Sadly we are seeing much bad science derived by statistical correlation without identification of the the physical processes linking cause and effect. Correlation itself, without understanding the underlying process, is insufficient to define a physical law.

The medical profession is among the worst offenders. As recent evidence, we are hearing that electromagnetic radiation correlates with various cancers without even understanding why.

Typical direct hit current is 15-30kA.
There is a very rare mechanism which gives rise to currents of 100kA+.
I don't believe any strikes get near 1MA.

The voltages present which you need to be concerned about tend to be
as a result of this current pulse causing a voltage drop due to the
impedance of the conductors and ground it passes through. For example,
a 25kA hit on some metalwork on a building which happens to be earthed
with an impedance of 4 ohms (not unreasonable for a drainpipe in
contact with the ground - mostly the ground impedance) would result in
that metalwork reaching 100kV.
Earthed electronic equipment near this could easily be damaged.
If your house electrical earth goes into the soil nearby, it might
well get pulsed to some proportion of this 100kV, say 25kV. If you
have a modem on your computer, it will suddenly see a 25kV pulse
between the computer side (connected to the household earth) and
the telephone line side (connected to earth a few miles away).
This could well flash over the line isolation components in the
modem, wrecking the modem and the computer. These are just examples
(based on some incidents I've seen), but should give a flavour.

Hi OM,

Sorry, I threw one supreme curve ball your way with my recommendation
for a "small" fractal.

WRONG WRONG WRONG

In fact I had simply steered you back to a large one. 16 meters indeed, that absurdity should have occurred to me as I was typing.

I was pressed to polish up my work, answer your post, and get something to my site. I don't think I was firing on all three cylinders there. For another hit, qsl.net's ftp server appears to be down.

So back to the "small" fractal solution. There still remain what I characterized as risk choices, but I'm afraid they would be very long shots.

Hi all,

Yes, Cecil is right. Due to the spread of the antenna inherent with fractal design, for some frequencies gain is developed along an axis. The curious thing is that this axis is not always aligned with any obvious physical structure. Even more confounding is that the axis of greatest gain twists and turns over frequency (large frequency changes, not small).

This discussion is, however, a product of my mistaken presentation of a large fractal as a small one. A most egregious error that is very misleading.

AHHH Practical Designs - humbug!

2063. Re: NEC4 Model of MI2 Fractal Loop Vs Random Geometry

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-15 00:00:00 UTC
From: VE9SRB <srbest@worldnet.att.net>
Message-ID: <jrsw5.15662$6f1.694725@bgtnsc05-news.ops.worldnet.att.net>
Source record: 180682

The performance comparison of the MI2 Fractal Loop and an arbitrarily chosen random wire geometry is complete. The conditions of comparison are as follows:

Both antennas have exactly the same overall total wire length. In this case: 27.56 meters

Both antennas occupy the same overall physical aperture size. In this case: 2.80 meters by 2.66 meters.

Both antennas have the same wire diameter: In this case: 0.64 cm

Both antennas are symmetric about the X and Y axis. This is a reasonable condition for any loop antenna.

Both antennas were modeled with NEC4. The validity of using NEC4 to model the MI2 Fractal Loop has been previously presented in a recent post. The NEC4 model of the MI2 Fractal Loop uses 500 wire segments. The NEC4 model of the random geometry uses 504 wire segments.

The antennas were modeled to determine the first and third resonant frequencies, the resonant resistance, the 2:1 SWR bandwidth wrt 50 ohms for the first resonance and the directivity at both resonant frequencies.

The Comparison:

MI2 Random

First Resonance: 15.749 MHz 15.403 MHz

Resonant Impedance: 28.4 ohms 27.3 ohms

Directivity: 2.14 dBi 2.13 dBi

Bandwidth (%): 1.27% 1.17%

Third Resonance: 28.65 MHz 28.105 MHz

Resonant Impedance: 19.0 ohms 16.9 ohms

Directivity: 4 dBi 5.8 dBi (see note below)

Note: The directivity of the antennas are different simply due to differing pattern shape. Based on a quick review of the patterns, it would be unreasonable to conclude one to be "better" than the other.

Conclusion: In my opinion, the performance of these antennas is so marginally different, it would be unreasonable to declare that one antenna

performs better than the other. What is important however is the significance of the Fractal geometry as compared to a non-Fractal geometry. The performance of the loop antenna is more a function of the overall wire length and the compression of the structure about the feedpoint (aperture size) than the Fractal geometry. With the exception of radiation pattern performance as a function of increasing frequency, it is safe to conclude that the geometry of the antenna is less significant than these other factors. Although certainly interesting, the Fractal nature of the antenna geometry is not the significant factor in determining the antenna performance.

Anyone interested in receiving GIF pictures of the antennas or the NEC files, please let me know.

73,
Steve, VE9SRB

Sept. 7, 2000

First off. To avoid any complication I am willing to sign a release of =
yours giving you full access to all medical records, test and opinions, =
all DDU of New Mexico records and reports and all Social Security =
medical records and reports plus any and all financial records including =
any and all disability social security benefits every paid me, all =
Medicare payments every made in my name, all medical and hospital =
records and any and all bills and payments you require to show that I am =
dead serious in asking you to please investigate this case because I am =
fighting a medical malpractice and conspiracy and fraud case PRO SE =
against some very powerful attorneys and doctors. Also if anyone of the =
doctors in this case still claims that their diagnosis especial on or =
around Feb. 1995 of my medical condition as that of Limb girdle muscular =
dystrophy is correct that doctor can immediately end this case simply by =
provide you and me with the medical evidence and test results they say =
they performed on me that especially shows their Feb. 1995 and dates =
thereafter diagnosis of LGMD and total disability is true and my 15-20 =
year medical condition was and is indeed that of LMGD. They can not =
provide you with any such evidence because it does not exist as =
defendants attorney has testify already in court to, and no test were =
every given by the two doctors to support their unbelievable =
misdiagnosis. Again, no blood test, muscle biopsy test, medical test =
were given that either doctor can point to that they say supports their =
false Feb. 1995 and dates thereafter misdiagnosis and claims that I am =
and have been for over 15 years totally disabled entitled to full social =
security and Medicare disability benefits. In fact prior to the Feb. =
1995 date and repeatedly after the Feb. 1995 date many doctor and =
experts in the field of neuro-muscular dystrophy have examined me and =
make blood test, EMG tests, muscle biopsy test and all have written that =
I do not now nor have I ever had LGMD with some going so far as to say =
that given the medical evidence present today and during the 1995 =
investigation NO DOCTOR could have mistakenly misdiagnosed my medical =
condition as that of LGMD. This was not only a misdiagnosis but once the =
misdiagnosis was discovered by me in early 1995 the doctor involved =
immediately began a cover up of the truth and conspired with a fellow =
doctor to continue the misdiagnosis knowing it was a lie and knowing =
that when they were advising social security and DDU in 1995 that I was =

totally disabled it was not true. The two doctors in this case had all =
the medical evidence from the UNMH-MDA clinic and the written words of =
the doctors and knew if they went ahead and intentionally diagnosed a =
false diagnosis it would be exactly that. If you investigate this case =
and open the District Court Records # CV-98-00271 you will find all =
medical evidence that I have submitted as evidence including the one =
doctors own late 1995 and early 1996 letter admitting he knew I was not =
ever totally disabled. I need help before these doctors and there =
lawyers get away with fraud, conspiracy and cover up. I have brought all =
the information to the judge in this case and he seems to not be =
listening instead overly concerned with rules of the court and not law =
of the land.

I have a question news media: When did the NMRA District Court and other =
Court rule book become law or statute onto themselves with the power to =
supersede statute and law and with so much power that they are looked =
unto by Judges and lawyers as laws unto themselves even though not one =
of them have ever been enacted into law or statute? How can a rule of =
court supersede statute and be held above statute with the power to =
overrule statute? Summary Judgment is a Rule of the court, created by =
judges and lawyers to skirt truth and real justice. When will the =
citizen of New Mexico see what attorneys and Judges have done taking =
over their court system and take that control back away from the Judges =
and the lawyers who seem to not have the citizens rights in mind? Who =
watches the attorneys and judges? Why is it that judges seem to be =
screaming and yelling at ordinary citizens who are seeking justice? =
Should we as ordinary citizens be afraid of the courts and the Judges =
knowing that a fancy lawyer can make a claims or accusation with no =
evidence to back such a claim or accusation and get away with it? In the =
case number included in this brief you will find specific examples of =
where a powerful lawyer has written their response to a medical law =
suit, not a medical malpractice lawsuit, in which the attorney from the =
very beginning makes not only bogus claim but out right un-provable and =
false claims that have been brought to the judges attention without the =
judge acting on one single one. If I went into court and lied throughout =
my questioning whether in writing or not I would be put in jail. Why =
aren=92t the lawyers held to the same standards. I thought you, as the =
media, were at the van guard always alert, always vigilant for the =
people. Then how did the lawyers take control of the courts away from =
the people?

The purpose of this letter is as follows:

THE ATTORNEY REQUIRED TO APPROACH THE MEDICAL MALPRACTICE COMMISSION =
PROVISION OF THE MEDICAL MALPRACTICE ACT Which denies individual =
citizens their constitutional rights to approach the courts HAS BEEN =
DECLARED UNCONSTITITIONAL IN CASE CV-98-00271 BECAUSE THEY DENY =
PLAINTIFF HIS CONSTITUTIONAL RIGHTS TO APPEAR BEFORE THE COURTS. =
PLAINTIFF IS TRYING TO DECLARE THE DISTRICT COURTS RULE BOOK WHEN IT =
SUPERSEDES LAW AND STATUTE UNCONSTITITUIONAL ESPECIALLY WHEN IT IS LOOK =
TO AS LAW AND STATUTE ONTO THEMSELVES CREATED BY THE COURTS AND FOR =

ATTORNEYS AND NOT BY THE PEOPLE AND FOR THE PEOPLE=85

Even if you don=92t look into case CV-98-00271 because of how =
complicated it is, and it involves the Muscular Dystrophy Association =
hospital clinic, which most media outlets support, Please, be at the =
next hearing to see how the courts don=92t look for truth and justice =
and have become so influenced by attorneys.

How can a Albuquerque High School Graduate, not schooled in the law, =
stand up Pro Se and fight a medical battle against a well entrenched =
medical profession hell bent on defeating anyone who comes up against =
them, with the same medical establishment having no interest in the =
truth about the persons health nor does it want to do the medical =
testing to see if one of its own created a knowingly and intentional =
false diagnosis? Why would physicians have a code of silence to protect =
an individual doctor who is allegedly hurting the very people the =
doctors claim they are helping? How can the same Albuquerque High School =
graduate go out and find a medical expert who is willing to testify that =
a Feb. 1995 diagnosis of plaintiffs medical condition as that of Limb =
Girdle Muscular Dystrophy was a negligent misdiagnosis and that from the =
medical evidence presented no doctor could have mistakenly diagnosed a =
disease as extreme as Limb Girdle Muscular Dystrophy? That even though =
the two doctor in the above named cased diagnosed and gave that =
diagnosis to the DDU of New Mexico and Social Security, the Plaintiff =
may not be totally disable as the two doctors claim? Was there any =
Medicare fraud as a direct result of the doctors alleged false diagnosis =
and did the doctor collect Medicare payments knowing that the patient =
did not have Limb Girdle Muscular Dystrophy and therefor may not have =
ever been totally disabled even though the one doctor continued said =
disabled diagnosis for over 15 years now? Is there Medicare and social =
security fraud going on here? How dare that same High School graduate =
fight a battle against injustice and indifference by the Court and is =
holding his owe against a powerful legal firm and legal precedent and =
think he will stand the test of time? HOW CAN THAT BE? Who does he think =
he is to be demanding justice and his right to the courts Pro se? Who =
does he think he is filing legal brief, notices and motions against us, =
the establishment as if he is a lawyer, not concerned with the rules of =
edict we attorneys have created for the courts to follow and implement =
as we dictate? How can a Pro Se high school Graduate think he can demand =
justice and think he can mention the word truth to the courts without =
severe consequences against him? This Pro Se individual dares to not =
follow our, the lawyers, lead in our endeavor to consume weeks and =
months on rules of the court and not laws by daring to constantly =
mention the facts and truth of the case? How dare him rock the boat of =
indifference and delays created by attorneys so they can collect =
exorbitant amounts of money doing nothing? How dare this Pro se =
individual approach the courts as an American citizen with inalienable =
rights and not be afraid of the courts or the judge sitting on the bench =
or what we, as attorneys, can get the judge to do to him? For we are =
friends of the Courts and some of the judges and our opinions count. We =
fraternize with some of the Judges unopposed with no fear that the media =

will ever question why we do that? We are higher that military officers =
who are not allowed to fraternize with enlisted personal? We are an =
entity unto ourselves, above examination by the media or anyone else. =
For we are the Lawyers of the court. All normal citizens should be =
afraid of what we, attorneys, can and will do to them if they dare =
challenge our authority before the courts. All normal citizens should be =
afraid of what we are doing to them and their rights behind closed doors =
unopposed by anyone or agency? We can paper you to death and you will =
loose on rules not law. How dare a Pro se individual go to the media and =
the public for help against us, the establishment and status quo, asking =
for legal and maybe even financial help thinking that the regular Joe =
cares one bit that we, the attorneys, have taken control of the courts =
and will not let it go back to the people without a fight! We are =
accountable to no one and we=92ll milk you dry of all you have before we =
throw you out like the garbage we think you are. The courts will do as =
we dictate because we have written the book of rules the courts have =
made laws unto themselves that supersede constitutionally created laws =
and statutes.=20

I hope you the media will not throw this in the garbage and do nothing =
for the people, but I must at least try. For if you just bother to read =
the information in especially District Court case #CV-98-00271 you will =
see what the above is about and how the lawyers have intentionally =
created a situation that benefits them and only them. I NEED HELP.. Who =
will help if you won=92t? One good thing about the computer revolution =
and especially the chat rooms and news and newsgroups organization on =
the Internet, even if the media chooses not to act, we still can get =
this out to the public.=20

I really don=92t understand, you are the media claiming that you are =
helping to look out for the welfare of the community but have you ever =
bothered to quietly and undercover sit in the District Court rooms of =
Bernalillo and see the unbelievable attitude that some of the Judges on =
the bench have towards the citizens of our state and how they are =
screaming and yelling possibly threatening regular people who only want =
justice. Do you periodically go undercover and sit in the various Court =
room to see for yourselves the attitudes of the judges on the bench and =
how they treat the people. Who monitors the Judges on the bench and =
their attitudes and the decisions that these judges are making? Do you =
even know or care what the Judges are doing and saying? Have Judges =
become so bitter with the people for what attorneys have done and =
continue to do unopposed that their attitudes, feelings and ruling are =
being adversely affected against the people? Why haven=92t the Judges =
been able to see through the theoretic and delay tactics Attorneys have =
created? IS IT BECAUSE JUDGES ARE ATTORNEYS THEMSELVES? Trained in the =
theoretic=92s of the show and not concerned with the law of the land. =
Does justice grind slowly down the road to completion as Attorneys have =
claimed or do attorneys intentionally create delays that the judges =
blame on the people? Why cant the people take back control of the court =
room? Are Judges fraternizing with attorneys, actually have coffee =
brakes with them, golfing with them? Why would an attorney claim to be =

friends with a judge and claim that she is going to have coffee with =
that judge? What is being discussed behind closed doors at these claimed =
coffee=92s and are lives being ruin because of such fraternizing? =
fraternization between a judge and a lawyer is a very dangerous thing =
especially when that lawyer makes insinuated comments that she=92s =
friends with the judge and she=92s off to have coffee with the =
judge-what are these statements for? More importantly: are the Judges =
ruling being in anyway influenced by any claimed friendships between a =
attorney and a Judge? When a Judge is sitting on a bench judging a case =
at hand, does that judge look at the attorney=92s and say blank is my =
friend and therefore he/she rulings are being adversely affected by such =
a friendship? Is the court system for the people, by the people and of =
the people or is it really as it looks, for the lawyer, by the lawyer =
and of the lawyer? Look into this case and see how can a lawyer do =
nothing for almost 2 years.

? Do you really think a court case can take 2 or more years because =
justice moves slowly? Or is it intentional on the parts of attorneys to =
intentionally delay and file one document at a time? Who fights for the =
people and how do you put a stop to these and other intentional delaying =
practices created by lawyers that serve no purpose for the client but =
does line the attorneys pockets? Once a case has started there is no =
Court charges for filing a motion in that pending case, yet lawyers are =
charging upwards of $500 to thousands for each and every motion they =
file, even when then file motions a piece at a time? To say that their =
time is that valuable and more valuable than their clients is bull? 90% =
of all motions and notices and documents are created by a lonely =
secretary who is not a lawyer and is not paid lawyers fees. When will =
the courts have an accounting of what lawyers are doing and the charges =
they are charging forcing an attorney to be accountable for the charges? =
Why doesn=92t a lawyer have a log book logging in the exact amount of =
time he spends on an individual case, stating the exact dates and time =
of day to justify their exorbitant charges? Why is a lawyer allowed to =
charge that much and milk a client dry? Who watches the lawyers?

TO WHOM IT MAY CONCERN, I AM NOT AN ATTORNEYS NOR DO I CLAIM TO BE NOR =
DO I HAVE THE EDUCATION TO DO AN ATTORNEYS JOB but because of a medical =
cover up intentionally created by the doctors in this case as testified =
to by the doctors own written letter submitted as evidence in this case =
and ignored by the courts and because of a false diagnosis given to =
social security and the Disability Determination Unit of the State of =
New Mexico I have be saddled with the disease of Limb girdle muscular =
dystrophy and claimed to be totally disabled collecting over the past =
15-20 years tens of thousands of dollars based on this one doctor =
knowingly false diagnosis. Once this information was given to the courts =
and social security in writing neither cared about the truth and social =
security stated it was not their business for me to go to court. After =
the court denied Defense attorneys motion to throw this case out of =
court and after the judge declared the Attorney Required Provision of =
the Medical Malpractice act unconstitutional, this case was sent to an =
arbitration meeting in which the arbitrator attorney stated to plaintiff =

that if I was seeking truth and justice I was at the wrong place. Even =
if the Court has the doctor written letter stated he knew Plaintiff was =
not totally disabled and continued the diagnosis anyway for decades =
passing that diagnosis to the DDU and Social Security, if you are =
looking for justice and the truth you would not find it in a court of =
law. It seem to me that court rules have become over law.=20

In case CV-98-00271 the Courts and attorneys have not mentioned the word =
truth nor has it mentioned the facts in this case nor has it fought over =
law and statute in this case for over two years. In fact in the majority =
of the Defendants briefs and motions filed in this case, incorrect =
statements and allegations are made with immunity from the court. Its as =
if the attorneys in any case can simply write what they want even if =
what they write is not true, has no baring on the case and has no =
evidence to support and when brought to the courts attention, the court =
simply ignores the evidence. How can a case be allowed to continue for =
over two years based on insinuation and not provable statements from =
attorneys? All the arguments are centered around court rules, summary =
judgment, discovery rules. When will the law be mentioned or the word =
truth or the facts.

When will the Courts go back to what they were created for, to judge the =
facts in a case, decide the truth from those facts and to dispense =
justice based on those facts and not on the court rules book or lawyers =
theoretical symphony training that was taught for the expressed purpose =
to sway the courts, judges and jury even though it is only a act, =
trained by tricky educators who know that symphony thoracic can most =
assuredly influence a judge and a jury even though it is only a play or =
a Act on the attorneys part. Example: A person is video taped throwing a =
brick through a window severely harming a person inside. That person =
without pressure writes that he did throw the brick. For two years in =
court those facts are not look at or even mentioned and the words =
looking for the truth has no baring on the case because lawyers have the =
judge tied up on rules of the court that have no legislative backing. =
With the lawyer for the accused actually trying to get the case thrown =
out of court by summary judgment thereby never mention the truth in the =
case. More importantly the person can actually get off without any =
justice simply based on rules of the court even though their is video =
tape that the person actually throw the brick through the window. That =
tape and the evidence has no baring in court proceedings for over 2 =
years, why? More importantly, the attorneys in the case are collecting =
exorbitant amounts of money for delay tactics and doing nothing. The =
Miranda rights are good and do what they are intended to do, protect the =
guilty and innocent from testifying against themselves. But if that =
defendant is running around telling everyone he did it and more =
importantly the court ain=92t going to do shit, when does the injured =
parties right supersede lawyers rules? Who created the District Courts =
Rule book and more importantly are they legislative law? How does rules =
made up by judges and lawyers for judges and lawyers become law unto =
themselves with the actual power to supersede legally constituted laws =
and statutes with the ability to overrule constitutional created laws =

and statutes?=20

Even though the New Mexico Supreme Court says that the District Court =
Rule book is law and statute, carrying the same weight as law and =
statutes and in fact superseding Law and statute constitutional CREATED =
by the legislature with the ability to overrule constitutional =
implemented law and statute, and in fact is placed above law and statute =
by the Judges of the Courts with the power to supersede law and statute, =
no where can you find one single rule of the District Court Rule book, =
including the summary Judgment rule, legislated into law or statute by =
the legislative branch of the New Mexican government. In the above =
mentioned case the Courts has used the Rule book of the District Courts =
as laws unto themselves using them to decide decisions on various issues =
from discovery to Summary Judgment without mentioning the clear evidence =
in this case and without even knowing what statute apply to this case =
and without ruling on the various Motion to Decide which Laws and =
statutes apply to this case. How can a Judge decide that a Rule, as =
Summary Judgment is, applies, when it has not decided on which statute =
governs this case even though it asked for such a Motion to be filed. =
What I feel has happened is that Attorneys have influenced and so =
corrupted the Courts and the Judges that somehow the Judges actually =
think that rules made up by attorneys for attorneys and not for the =
people have been declared constitutional law by the Judicial branch of =
the government and not through the constitutional elected legislative =
branch. No where in any legislative created statute does the courts rule =
book rules become law.=20

What I don=92t understand is why the media, with claims that they were =
created to look after the interest of the people, has been silent on =
this vital issue. And I don=92t understand why the media, who has the =
power to influence the people into action, has not looked at the =
unbelievable delaying tactics attorneys are using in court for the only =
reason but to collect exorbitant amount of unjustified moneys for doing =
nothing but delaying? How does a regular citizen even know that when the =
lawyer on the other side of the desk is saying its going to take month, =
maybe even years for a final outcome in their case, its not because =
justice moves slowly, it simply because the attorneys are delaying the =
final outcome and intentionally filing one document at a time to stretch =
the case out years because it is in their best interest financially to =
do so. Medical experts who are hired to testify are doing the same =
thing. They know certain test will be required to support their hired =
and paid for testimony that could easily be done in days, they stretch =
down the road months by doing one test at a time. Who stops the lawyers =
and experts? Who keeps a watchful eye on them making sure they are not =
testifying for the money? Simple example: a back x-ray from you back =
doctor cost $100 to produce and $200 for him to evaluate. A expert =
charges $500 for that x-ray and 1-5000 for his evaluation and then more =
for is on bench testimony- why? Because the expert is strictly in it for =
the money the lawyers can pay him with and not for truth or justice? =
Seems to me that the courts should look at expert testimony with =
suspicion for what it is, hired and paid for testimony and not the =

truth. If an expert is required, and the law says one is required then =
why hasn=92t anyone taken that responsibly out of the hands of the =
lawyers and experts and put it into a neutral hand with doctors and =
experts who have no financial gain to gain and therefore testifies on =
the truth and not on paid slanted truth? Why haven=92t you, the media, =
bothered to look at expert testimony for what it really is. A expert who =
has prostituted his license and integrity for money and only money? Will =
a expert look at a person damaged if that person has no money? How can =
we the people stop the courts practices of using attorney hired =
experts=85 Example: As the media know, social security disability =
Attorneys are intentionally dragging out disability determinations =
decisions for 12 months to 2 years as standard practicing procedures, =
which decision could easily be made in one month, because the lawyers =
get 33 and 1/3 percent of all back pay and 331/3% of 1-2 years is quite =
a lot of money especially when they do nothing but collect money.=20

Why has the court developed so many confusing rules and regulations that =
a simple man can not approach the courts pro se? Do the judges ask for =
an accounting of the amount the attorneys are charging and the delays =
the attorney ask for? ARE ATTORNEYS WHAT THEY THINK THEY ARE, INITITIES =
ONTO THEMSELVES? If a attorney is doing nothing and taking advantage of =
a clients depression, who do you go to, to stop that attorney Second: =
Are judges fraternizing with Attorneys and for what purpose? Are =
attorneys actually going into Judges offices and sitting down and =
drinking coffee or tea with Judges and shooting the shit as this one =
attorney claims? You know, the military has a very important rule that =
Military officers are not allowed to fraternize with enlisted personal =
for a very good reason. So the look of even a partial amount of =
favoritism will not be displayed. I think this rule applies here. Surely =
Judges and Attorneys are not better than officers in the military. If =
Judges and attorneys are claiming that nothing is going on then why the =
fraternization? If these coffee and tea brakes are simply that, then why =
does this attorney go to great length to mention that he/she are good =
friends with the particular Judge and that they actually are off to have =
coffee with my dear friend? How do we find out if there is such a rule =
against such fraternizing and if not who regulates such fraternizing to =
be sure nothing improper is being done behind closed doors? Who keeps an =
eye on those activities between Judges and attorneys? A regular citizen, =
who has been harmed by a doctor and who covers up that harm, should have =
no fear to approach a judge for help and no fear that their rights will =
be trampled on because the opposing counsel is going to make sure that =
this case is kept in the courts so long that it will ruin the damaged =
party financially? Who is looking at the cost that attorneys are =
charging. A domestic case that is filed cost at the most $200 to file. =
All Motion have no court charges yet attorneys charge Upwards of $500 or =
more for supposedly Motions that have no court charges and that may be =
one page long. Who does a regular citizen go to, to find out if she is =
being taken advantaged off by a lawyer who know the client is scared or =
in manic depression? Please Help?=20

Now back to my case still pending in court.

If what the doctor wrote in his 1995 and 1996 letters are true, that he =
knew for decades that plaintiff was not totally disabled, the =
implication are mind boggling. This doctor was and is instrumental in =
getting plaintiff full disability social security benefits and =
continuing full disability benefits for almost 20 years now even though =
he writes that he knew for decades that plaintiff was not totally =
disabled but did not bother telling anyone, including plaintiff, DDU, =
social security, other hospital, doctors. According to the experts at =
the UNMH MDA Clinic this would indicate that plaintiff does not now nor =
has he ever had LGMD nor was plaintiff ever totally disabled for almost =
20 years now even though the doctor in this case continually diagnosed =
it for 15 years with out one single medical test record to support his =
diagnosis

The media needs to understand clearly this that the doctor involved will =
not or can not produce one single medical or lab test report, one single =
EMG test report, one single blood test report, one single muscle biopsy =
test report that the two doctors claims they performed on plaintiff in =
Feb. 1995 and dates thereafter that they claim support their Feb. 1995 =
and date thereafter false diagnosis of plaintiff medical condition as =
LGMD (Limb Girdle Muscular Dystrophy) and total disability that they not =
only passed off as truth to plaintiff, but also to Dr. Hamilton of the =
DDU, the DDU, and social security, and if this same doctor will not or =
can not produce one single medical or lab test report, one single EMG =
test report, one single blood test report, one single muscle biopsy test =
report that he claims he did over a 15 or more year period while he was =
plaintiff doctor that that kept this patient on total disability social =
security and Medicare benefits for over 15 years and this same doctor =
can not or will not produce one single medical record that supports his =
15 or more year intentional and false diagnosis of plaintiffs medical =
condition as LGMD and total disability that he knowingly and =
intentionally pass to the DDU, DVR, social security, to keep his patient =
on total disability social security benefits and Medicare.

"The implications are mine boggling: For years - This Doctor looked my =
family and me, the DDU and Social Security straight in the eyes and knew =
he was lying and passing a false diagnosis". That=92s Why go public. If =
I don=92t the courts will continue to not worry about the truth and will =
keep being consumed with its rules of court that the courts have =
elevated above law and order and truth! I need help from you the media =
to get this out into the public domain, to get it out of the shadows as =
it were so that no judge or lawyer will be able to hid in the dark =
again.

Do you realize that there is a constitutional battle going on in the =
District Court of Bernalillo county, Albuquerque, New Mexico, Dis. CT. =
No. __CV-98-00271___, W. Daniel Schneider, presiding justice, Over the =
attorney "Required" provision of the Medical Malpractice Act and the =
RULES of the court especially what the court calls summary judgment, =
that is slowly but surely headed for the U.S. Supreme Court. Do you =
realize that an ordinary Albuquerque High and TVI School Graduate, has =
not only challenged the District Court system, he has fought a fine =

fight "PRO SE" against a powerful attorney establishment, getting =
Justice Schneider to declare the "Attorney Provision of the Act" =
unconstitutional!

All either physician has to do is provide proof positive to this court, =
plaintiff and the media that shows that either one of these physicians =
bothered to do the bare minimum of medical and lab test, EMG test, in =
Feb. 1995 and dates thereafter that they say supports their diagnosis of =
LGMD and total disability that plaintiff can present to social security, =
the DDU and the court and say see, I do have LGMD and am totally =
disabled and am legally entitled to total disability benefits from =
social security for the rest of my life and you can=92t take it away or =
demand pay back. ITS THAT SIMPLE. Give me proof that Dr. Gregg ever =
bothered to periodically re-evaluate my medical condition despite =
several DDU, social security re-determinations that he was the only =
doctor. That support the years of pain and suffering, hospital stays, =
medicines, brain seizures, congestive heart failures, lost of home, =
wife, potential. Please asked the doctors=85=20

I asks this news organization to please at least go to the court house =
and look up and read these cases records and especially all the evidence =
placed before the judge and please present this case publicly to the =
people so that the attorneys can not bury it under a pretense of =
innocence and court rule. I am fighting an uphill battle that has grown =
very difficult to fight. I ask the ordinary people out there who are =
seeking equal justice under the law to Help. Medical experts and =
documents cost thousands. I am at my roads end. Without your financial =
support the doctors will win by default and no money.

Sincerely your,

Frank T. McMurtrey

Sept. 7, 2000

First off. To avoid any complication I am willing to =
sign a=20
release of yours giving you full access to all medical records, test and =

opinions, all DDU of New Mexico records and reports and all Social =
Security=20
medical records and reports plus any and all financial records including =
any and=20
all disability social security benefits every paid me, all Medicare =

payments=20
every made in my name, all medical and hospital records and any and all =
bills=20
and payments you require to show that I am dead serious in asking you to =
please=20
investigate this case because I am fighting a medical malpractice and =
conspiracy=20
and fraud case PRO SE against some very powerful attorneys and doctors. =
Also if=20
anyone of the doctors in this case still claims that their diagnosis =
especial on=20
or around Feb. 1995 of my medical condition as that of Limb girdle =
muscular=20
dystrophy is correct that doctor can immediately end this case simply by =
provide=20
you and me with the medical evidence and test results they say they =
performed on=20
me that especially shows their Feb. 1995 and dates thereafter diagnosis =
of LGMD=20
and total disability is true and my 15-20 year medical condition was and =
is=20
indeed that of LMGD. They can not provide you with any such evidence =
because it=20
does not exist as defendants attorney has testify already in court to, =
and no=20
test were every given by the two doctors to support their unbelievable=20
misdiagnosis. Again, no blood test, muscle biopsy test, medical test =
were given=20
that either doctor can point to that they say supports their false Feb. =
1995 and=20
dates thereafter misdiagnosis and claims that I am and have been for =
over 15=20
years totally disabled entitled to full social security and Medicare =
disability=20
benefits. In fact prior to the Feb. 1995 date and repeatedly after the =
Feb. 1995=20
date many doctor and experts in the field of neuro-muscular dystrophy =
have=20
examined me and make blood test, EMG tests, muscle biopsy test and all =
have=20
written that I do not now nor have I ever had LGMD with some going so =
far as to=20
say that given the medical evidence present today and during the 1995=20
investigation NO DOCTOR could have mistakenly misdiagnosed my medical =
condition=20
as that of LGMD. This was not only a misdiagnosis but once the =
misdiagnosis was=20
discovered by me in early 1995 the doctor involved immediately began a =
cover up=20
of the truth and conspired with a fellow doctor to continue the =

misdiagnosis=20
knowing it was a lie and knowing that when they were advising social =
security=20
and DDU in 1995 that I was totally disabled it was not true. The two =
doctors in=20
this case had all the medical evidence from the UNMH-MDA clinic and the =
written=20
words of the doctors and knew if they went ahead and intentionally =
diagnosed a=20
false diagnosis it would be exactly that. If you investigate this case =
and open=20
the District Court Records # CV-98-00271 =
you will=20
find all medical evidence that I have submitted as evidence including =
the one=20
doctors own late 1995 and early 1996 letter admitting he knew I was not =
ever=20
totally disabled. I need help before these doctors and there lawyers get =
away=20
with fraud, conspiracy and cover up. I have brought all the information =
to the=20
judge in this case and he seems to not be listening instead overly =
concerned=20
with rules of the court and not law of the land.

I have a question news media: When did the NMRA =
District Court=20
and other Court rule book become law or statute onto themselves with the =
power=20
to supersede statute and law and with so much power that they are looked =
unto by=20
Judges and lawyers as laws unto themselves even though not one of them =
have ever=20
been enacted into law or statute? How can a rule of court supersede =
statute and=20
be held above statute with the power to overrule statute? Summary =
Judgment is a=20
Rule of the court, created by judges and lawyers to skirt truth and real =

justice. When will the citizen of New Mexico see what attorneys and =
Judges have=20
done taking over their court system and take that control back away from =
the=20
Judges and the lawyers who seem to not have the citizens rights in mind? =
Who=20
watches the attorneys and judges? Why is it that judges seem to be =
screaming and=20
yelling at ordinary citizens who are seeking justice? Should we as =
ordinary=20
citizens be afraid of the courts and the Judges knowing that a fancy =
lawyer can=20

make a claims or accusation with no evidence to back such a claim or =
accusation=20
and get away with it? In the case number included in this brief you will =
find=20
specific examples of where a powerful lawyer has written their response =
to a=20
medical law suit, not a medical malpractice lawsuit, in which the =
attorney from=20
the very beginning makes not only bogus claim but out right un-provable =
and=20
false claims that have been brought to the judges attention without the =
judge=20
acting on one single one. If I went into court and lied throughout my=20
questioning whether in writing or not I would be put in jail. Why =
aren’t=20
the lawyers held to the same standards. I thought you, as the media, =
were at the=20
van guard always alert, always vigilant for the people. Then how did the =
lawyers=20
take control of the courts away from the people?

The purpose of this letter is as follows:

THE ATTORNEY REQUIRED TO APPROACH THE MEDICAL =
MALPRACTICE=20
COMMISSION PROVISION OF THE MEDICAL MALPRACTICE ACT Which denies =
individual=20
citizens their constitutional rights to approach the courts HAS BEEN =
DECLARED=20
UNCONSTITITIONAL IN CASE CV-98-00271 BECAUSE THEY DENY PLAINTIFF HIS=20
CONSTITUTIONAL RIGHTS TO APPEAR BEFORE THE COURTS. PLAINTIFF IS TRYING =
TO=20
DECLARE THE DISTRICT COURTS RULE BOOK WHEN IT SUPERSEDES LAW AND STATUTE =

UNCONSTITITUIONAL ESPECIALLY WHEN IT IS LOOK TO AS LAW AND STATUTE ONTO=20
THEMSELVES CREATED BY THE COURTS AND FOR ATTORNEYS AND NOT BY THE PEOPLE =
AND FOR=20
THE PEOPLE…

Even if you don’t look into case CV-98-00271 =
because of=20
how complicated it is, and it involves the Muscular Dystrophy =
Association=20
hospital clinic, which most media outlets support, Please, be at the =
next=20
hearing to see how the courts don’t look for truth and justice and =
have=20
become so influenced by attorneys.

How can a Albuquerque High School Graduate, not =
schooled in the=20
law, stand up Pro Se and fight a medical battle against a well =

entrenched=20
medical profession hell bent on defeating anyone who comes up against =
them, with=20
the same medical establishment having no interest in the truth about the =
persons=20
health nor does it want to do the medical testing to see if one of its =
own=20
created a knowingly and intentional false diagnosis? Why would =
physicians have a=20
code of silence to protect an individual doctor who is allegedly hurting =
the=20
very people the doctors claim they are helping? How can the same =
Albuquerque=20
High School graduate go out and find a medical expert who is willing to =
testify=20
that a Feb. 1995 diagnosis of plaintiffs medical condition as that of =
Limb=20
Girdle Muscular Dystrophy was a negligent misdiagnosis and that from the =
medical=20
evidence presented no doctor could have mistakenly diagnosed a disease =
as=20
extreme as Limb Girdle Muscular Dystrophy? That even though the two =
doctor in=20
the above named cased diagnosed and gave that diagnosis to the DDU of =
New Mexico=20
and Social Security, the Plaintiff may not be totally disable as the two =
doctors=20
claim? Was there any Medicare fraud as a direct result of the doctors =
alleged=20
false diagnosis and did the doctor collect Medicare payments knowing =
that the=20
patient did not have Limb Girdle Muscular Dystrophy and therefor may not =
have=20
ever been totally disabled even though the one doctor continued said =
disabled=20
diagnosis for over 15 years now? Is there Medicare and social security =
fraud=20
going on here? How dare that same High School graduate fight a battle =
against=20
injustice and indifference by the Court and is holding his owe against a =

powerful legal firm and legal precedent and think he will stand the test =
of=20
time? HOW CAN THAT BE? Who does he think he is to be demanding justice =
and his=20
right to the courts Pro se? Who does he think he is filing legal brief, =
notices=20
and motions against us, the establishment as if he is a lawyer, not =
concerned=20
with the rules of edict we attorneys have created for the courts to =

follow and=20
implement as we dictate? How can a Pro Se high school Graduate think he =
can=20
demand justice and think he can mention the word truth to the courts =
without=20
severe consequences against him? This Pro Se individual dares to not =
follow our,=20
the lawyers, lead in our endeavor to consume weeks and months on rules =
of the=20
court and not laws by daring to constantly mention the facts and truth =
of the=20
case? How dare him rock the boat of indifference and delays created by =
attorneys=20
so they can collect exorbitant amounts of money doing nothing? How dare =
this Pro=20
se individual approach the courts as an American citizen with =
inalienable rights=20
and not be afraid of the courts or the judge sitting on the bench or =
what we, as=20
attorneys, can get the judge to do to him? For we are friends of the =
Courts and=20
some of the judges and our opinions count. We fraternize with some of =
the Judges=20
unopposed with no fear that the media will ever question why we do that? =
We are=20
higher that military officers who are not allowed to fraternize with =
enlisted=20
personal? We are an entity unto ourselves, above examination by the =
media or=20
anyone else. For we are the Lawyers of the court. All normal citizens =
should be=20
afraid of what we, attorneys, can and will do to them if they dare =
challenge our=20
authority before the courts. All normal citizens should be afraid of =
what we are=20
doing to them and their rights behind closed doors unopposed by anyone =
or=20
agency? We can paper you to death and you will loose on rules not law. =
How dare=20
a Pro se individual go to the media and the public for help against us, =
the=20
establishment and status quo, asking for legal and maybe even financial =
help=20
thinking that the regular Joe cares one bit that we, the attorneys, have =
taken=20
control of the courts and will not let it go back to the people without =
a fight!=20
We are accountable to no one and we’ll milk you dry of all you =
have before=20
we throw you out like the garbage we think you are. The courts will do =

as we=20
dictate because we have written the book of rules the courts have made =
laws unto=20
themselves that supersede constitutionally created laws and statutes. =

I hope you the media will not throw this in the =
garbage and do=20
nothing for the people, but I must at least try. For if you just bother =
to read=20
the information in especially District Court case #CV-98-00271 you will =
see what=20
the above is about and how the lawyers have intentionally created a =
situation=20
that benefits them and only them. I NEED HELP.. Who will help if you=20
won't? One good thing about the computer revolution and especially =
the=20
chat rooms and news and newsgroups organization on the Internet, even if =
the=20
media chooses not to act, we still can get this out to the public.

I really don't understand, you are the media =
claiming=20
that you are helping to look out for the welfare of the community but =
have you=20
ever bothered to quietly and undercover sit in the District Court rooms =
of=20
Bernalillo and see the unbelievable attitude that some of the Judges on =
the=20
bench have towards the citizens of our state and how they are screaming =
and=20
yelling possibly threatening regular people who only want justice. Do =
you=20
periodically go undercover and sit in the various Court room to see for=20
yourselves the attitudes of the judges on the bench and how they treat =
the=20
people. Who monitors the Judges on the bench and their attitudes and the =

decisions that these judges are making? Do you even know or care what =
the Judges=20
are doing and saying? Have Judges become so bitter with the people for =
what=20
attorneys have done and continue to do unopposed that their attitudes, =
feelings=20
and ruling are being adversely affected against the people? Why =
haven't=20
the Judges been able to see through the theoretic and delay tactics =
Attorneys=20
have created? IS IT BECAUSE JUDGES ARE ATTORNEYS THEMSELVES? Trained in =
the=20
theoretic's of the show and not concerned with the law of the =
land. Does=20

justice grind slowly down the road to completion as Attorneys have =
claimed or do=20
attorneys intentionally create delays that the judges blame on the =
people? Why=20
cant the people take back control of the court room? Are Judges =
fraternizing=20
with attorneys, actually have coffee brakes with them, golfing with =
them? Why=20
would an attorney claim to be friends with a judge and claim that she is =
going=20
to have coffee with that judge? What is being discussed behind closed =
doors at=20
these claimed coffee's and are lives being ruin because of such=20
fraternizing? fraternization between a judge and a lawyer is a very =
dangerous=20
thing especially when that lawyer makes insinuated comments that =
she's=20
friends with the judge and she's off to have coffee with the =
judge-what=20
are these statements for? More importantly: are the Judges ruling =
being in=20
anyway influenced by any claimed friendships between a attorney and a =
Judge?=20
When a Judge is sitting on a bench judging a case at hand, does that =
judge look=20
at the attorney's and say blank is my friend and therefore he/she =
rulings=20
are being adversely affected by such a friendship? Is the court =
system=20
for the people, by the people and of the people or is it really as it =
looks, for=20
the lawyer, by the lawyer and of the lawyer? Look into this case and see =
how can=20
a lawyer do nothing for almost 2 years.

? Do you really think a court case can take 2 or more =
years=20
because justice moves slowly? Or is it intentional on the parts of =
attorneys to=20
intentionally delay and file one document at a time? Who fights for the =
people=20
and how do you put a stop to these and other intentional delaying =
practices=20
created by lawyers that serve no purpose for the client but does line =
the=20
attorneys pockets? Once a case has started there is no Court charges for =
filing=20
a motion in that pending case, yet lawyers are charging upwards of $500 =
to=20
thousands for each and every motion they file, even when then file =

motions a=20
piece at a time? To say that their time is that valuable and more =
valuable than=20
their clients is bull? 90% of all motions and notices and documents are =
created=20
by a lonely secretary who is not a lawyer and is not paid lawyers fees. =
When=20
will the courts have an accounting of what lawyers are doing and the =
charges=20
they are charging forcing an attorney to be accountable for the charges? =
Why=20
doesn't a lawyer have a log book logging in the exact amount of =
time he=20
spends on an individual case, stating the exact dates and time of day to =
justify=20
their exorbitant charges? Why is a lawyer allowed to charge that much =
and milk a=20
client dry? Who watches the lawyers?

TO WHOM IT MAY CONCERN, I AM NOT AN ATTORNEYS NOR DO =
I CLAIM TO=20
BE NOR DO I HAVE THE EDUCATION TO DO AN ATTORNEYS JOB but because of a =
medical=20
cover up intentionally created by the doctors in this case as testified =
to by=20
the doctors own written letter submitted as evidence in this case and =
ignored by=20
the courts and because of a false diagnosis given to social security and =
the=20
Disability Determination Unit of the State of New Mexico I have be =
saddled with=20
the disease of Limb girdle muscular dystrophy and claimed to be totally =
disabled=20
collecting over the past 15-20 years tens of thousands of dollars based =
on this=20
one doctor knowingly false diagnosis. Once this information was given to =
the=20
courts and social security in writing neither cared about the truth and =
social=20
security stated it was not their business for me to go to court. After =
the court=20
denied Defense attorneys motion to throw this case out of court and =
after the=20
judge declared the Attorney Required Provision of the Medical =
Malpractice act=20
unconstitutional, this case was sent to an arbitration meeting in which =
the=20
arbitrator attorney stated to plaintiff that if I was seeking truth and =
justice=20
I was at the wrong place. Even if the Court has the doctor written =

letter stated=20
he knew Plaintiff was not totally disabled and continued the diagnosis =
anyway=20
for decades passing that diagnosis to the DDU and Social Security, if =
you are=20
looking for justice and the truth you would not find it in a court of =
law. It=20
seem to me that court rules have become over law.

In case CV-98-00271 the Courts and attorneys have not =
mentioned=20
the word truth nor has it mentioned the facts in this case nor has it =
fought=20
over law and statute in this case for over two years. In fact in the =
majority of=20
the Defendants briefs and motions filed in this case, incorrect =
statements and=20
allegations are made with immunity from the court. Its as if the =
attorneys in=20
any case can simply write what they want even if what they write is not =
true,=20
has no baring on the case and has no evidence to support and when =
brought to the=20
courts attention, the court simply ignores the evidence. How can a case =
be=20
allowed to continue for over two years based on insinuation and not =
provable=20
statements from attorneys? All the arguments are centered around court =
rules,=20
summary judgment, discovery rules. When will the law be mentioned or the =
word=20
truth or the facts.

When will the Courts go back to what they were =
created for, to=20
judge the facts in a case, decide the truth from those facts and to =
dispense=20
justice based on those facts and not on the court rules book or lawyers=20
theoretical symphony training that was taught for the expressed purpose =
to sway=20
the courts, judges and jury even though it is only a act, trained by =
tricky=20
educators who know that symphony thoracic can most assuredly influence a =
judge=20
and a jury even though it is only a play or a Act on the attorneys part. =

Example: A person is video taped throwing a brick through a window =
severely=20
harming a person inside. That person without pressure writes that he did =
throw=20
the brick. For two years in court those facts are not look at or even =

mentioned=20
and the words looking for the truth has no baring on the case because =
lawyers=20
have the judge tied up on rules of the court that have no legislative =
backing.=20
With the lawyer for the accused actually trying to get the case thrown =
out of=20
court by summary judgment thereby never mention the truth in the case. =
More=20
importantly the person can actually get off without any justice simply =
based on=20
rules of the court even though their is video tape that the person =
actually=20
throw the brick through the window. That tape and the evidence has no =
baring in=20
court proceedings for over 2 years, why? More importantly, the attorneys =
in the=20
case are collecting exorbitant amounts of money for delay tactics and =
doing=20
nothing. The Miranda rights are good and do what they are intended to =
do,=20
protect the guilty and innocent from testifying against themselves. But =
if that=20
defendant is running around telling everyone he did it and more =
importantly the=20
court ain’t going to do shit, when does the injured parties right=20
supersede lawyers rules? Who created the District Courts Rule book and =
more=20
importantly are they legislative law? How does rules made up by judges =
and=20
lawyers for judges and lawyers become law unto themselves with the =
actual power=20
to supersede legally constituted laws and statutes with the ability to =
overrule=20
constitutional created laws and statutes?

Even though the New Mexico Supreme Court says that =
the District=20
Court Rule book is law and statute, carrying the same weight as law and =
statutes=20
and in fact superseding Law and statute constitutional CREATED by the=20
legislature with the ability to overrule constitutional implemented law =
and=20
statute, and in fact is placed above law and statute by the Judges of =
the Courts=20
with the power to supersede law and statute, no where can you find one =
single=20
rule of the District Court Rule book, including the summary Judgment =
rule,=20
legislated into law or statute by the legislative branch of the New =

Mexican=20
government. In the above mentioned case the Courts has used the Rule =
book of the=20
District Courts as laws unto themselves using them to decide decisions =
on=20
various issues from discovery to Summary Judgment without mentioning the =
clear=20
evidence in this case and without even knowing what statute apply to =
this case=20
and without ruling on the various Motion to Decide which Laws and =
statutes apply=20
to this case. How can a Judge decide that a Rule, as Summary Judgment =
is,=20
applies, when it has not decided on which statute governs this case even =
though=20
it asked for such a Motion to be filed. What I feel has happened is that =

Attorneys have influenced and so corrupted the Courts and the Judges =
that=20
somehow the Judges actually think that rules made up by attorneys for =
attorneys=20
and not for the people have been declared constitutional law by the =
Judicial=20
branch of the government and not through the constitutional elected =
legislative=20
branch. No where in any legislative created statute does the courts rule =
book=20
rules become law.

What I don’t understand is why the media, with =
claims=20
that they were created to look after the interest of the people, has =
been silent=20
on this vital issue. And I don’t understand why the media, who has =
the=20
power to influence the people into action, has not looked at the =
unbelievable=20
delaying tactics attorneys are using in court for the only reason but to =
collect=20
exorbitant amount of unjustified moneys for doing nothing but delaying? =
How does=20
a regular citizen even know that when the lawyer on the other side of =
the desk=20
is saying its going to take month, maybe even years for a final outcome =
in their=20
case, its not because justice moves slowly, it simply because the =
attorneys are=20
delaying the final outcome and intentionally filing one document at a =
time to=20
stretch the case out years because it is in their best interest =
financially to=20

do so. Medical experts who are hired to testify are doing the same =
thing. They=20
know certain test will be required to support their hired and paid for =
testimony=20
that could easily be done in days, they stretch down the road months by =
doing=20
one test at a time. Who stops the lawyers and experts? Who keeps a =
watchful eye=20
on them making sure they are not testifying for the money? Simple =
example: a=20
back x-ray from you back doctor cost $100 to produce and $200 for him to =

evaluate. A expert charges $500 for that x-ray and 1-5000 for his =
evaluation and=20
then more for is on bench testimony- why? Because the expert is strictly =
in it=20
for the money the lawyers can pay him with and not for truth or justice? =
Seems=20
to me that the courts should look at expert testimony with suspicion for =
what it=20
is, hired and paid for testimony and not the truth. If an expert is =
required,=20
and the law says one is required then why hasn't anyone taken that =

responsibly out of the hands of the lawyers and experts and put it into =
a=20
neutral hand with doctors and experts who have no financial gain to gain =
and=20
therefore testifies on the truth and not on paid slanted truth? Why=20
haven't you, the media, bothered to look at expert testimony for =
what it=20
really is. A expert who has prostituted his license and integrity for =
money and=20
only money? Will a expert look at a person damaged if that person has no =
money?=20
How can we the people stop the courts practices of using attorney hired=20
experts… Example: As the media know, social security disability =
Attorneys=20
are intentionally dragging out disability determinations decisions for =
12 months=20
to 2 years as standard practicing procedures, which decision could =
easily be=20
made in one month, because the lawyers get 33 and 1/3 percent of all =
back pay=20
and 331/3% of 1-2 years is quite a lot of money especially when they do =
nothing=20
but collect money.

Why has the court developed so many confusing rules =
and=20
regulations that a simple man can not approach the courts pro se? Do the =

judges=20
ask for an accounting of the amount the attorneys are charging and the =
delays=20
the attorney ask for? ARE ATTORNEYS WHAT THEY THINK THEY ARE, INITITIES =
ONTO=20
THEMSELVES? If a attorney is doing nothing and taking advantage of a =
clients=20
depression, who do you go to, to stop that attorney Second: Are judges=20
fraternizing with Attorneys and for what purpose? Are attorneys actually =
going=20
into Judges offices and sitting down and drinking coffee or tea with =
Judges and=20
shooting the shit as this one attorney claims? You know, the military =
has a very=20
important rule that Military officers are not allowed to fraternize with =

enlisted personal for a very good reason. So the look of even a partial =
amount=20
of favoritism will not be displayed. I think this rule applies here. =
Surely=20
Judges and Attorneys are not better than officers in the military. If =
Judges and=20
attorneys are claiming that nothing is going on then why the =
fraternization? If=20
these coffee and tea brakes are simply that, then why does this attorney =
go to=20
great length to mention that he/she are good friends with the particular =
Judge=20
and that they actually are off to have coffee with my dear friend? How =
do we=20
find out if there is such a rule against such fraternizing and if not =
who=20
regulates such fraternizing to be sure nothing improper is being done =
behind=20
closed doors? Who keeps an eye on those activities between Judges and =
attorneys?=20
A regular citizen, who has been harmed by a doctor and who covers up =
that harm,=20
should have no fear to approach a judge for help and no fear that their =
rights=20
will be trampled on because the opposing counsel is going to make sure =
that this=20
case is kept in the courts so long that it will ruin the damaged party=20
financially? Who is looking at the cost that attorneys are charging. A =
domestic=20
case that is filed cost at the most $200 to file. All Motion have no =
court=20
charges yet attorneys charge Upwards of $500 or more for supposedly =
Motions that=20
have no court charges and that may be one page long. Who does a regular =

citizen=20
go to, to find out if she is being taken advantaged off by a lawyer who =
know the=20
client is scared or in manic depression? Please Help?

Now back to my case still pending in court.

If what the doctor wrote in his 1995 and 1996 letters =
are true,=20
that he knew for decades that plaintiff was not totally disabled, the=20
implication are mind boggling. This doctor was and is instrumental in =
getting=20
plaintiff full disability social security benefits and continuing full=20
disability benefits for almost 20 years now even though he writes that =
he knew=20
for decades that plaintiff was not totally disabled but did not bother =
telling=20
anyone, including plaintiff, DDU, social security, other hospital, =
doctors.=20
According to the experts at the UNMH MDA Clinic this would indicate that =

plaintiff does not now nor has he ever had LGMD nor was plaintiff ever =
totally=20
disabled for almost 20 years now even though the doctor in this case =
continually=20
diagnosed it for 15 years with out one single medical test record to =
support his=20
diagnosis

The media needs to understand clearly this that the =
doctor=20
involved will not or can not produce one single medical or lab test =
report, one=20
single EMG test report, one single blood test report, one single muscle =
biopsy=20
test report that the two doctors claims they performed on plaintiff in =
Feb. 1995=20
and dates thereafter that they claim support their Feb. 1995 and date =
thereafter=20
false diagnosis of plaintiff medical condition as LGMD (Limb Girdle =
Muscular=20
Dystrophy) and total disability that they not only passed off as truth =
to=20
plaintiff, but also to Dr. Hamilton of the DDU, the DDU, and social =
security,=20
and if this same doctor will not or can not produce one single medical =
or lab=20
test report, one single EMG test report, one single blood test report, =
one=20
single muscle biopsy test report that he claims he did over a 15 or more =
year=20

period while he was plaintiff doctor that that kept this patient on =
total=20
disability social security and Medicare benefits for over 15 years and =
this same=20
doctor can not or will not produce one single medical record that =
supports his=20
15 or more year intentional and false diagnosis of plaintiffs medical =
condition=20
as LGMD and total disability that he knowingly and intentionally pass to =
the=20
DDU, DVR, social security, to keep his patient on total disability =
social=20
security benefits and Medicare.

"The implications are mine boggling: =
For years - This Doctor looked my family and me, the DDU and =
Social=20
Security straight in the eyes and knew he was lying and passing a false=20
diagnosis". That’s Why go =
public. If I=20
don’t the courts will continue to not worry about the truth and =
will keep=20
being consumed with its rules of court that the courts have elevated =
above law=20
and order and truth! I need help from you the media to get this out into =
the=20
public domain, to get it out of the shadows as it were so that no judge =
or=20
lawyer will be able to hid in the dark again.

Do you realize that there is a constitutional battle =
going on=20
in the District Court of Bernalillo county, Albuquerque, New Mexico, =
Dis. CT.=20
No. __CV-98-00271___, W. Daniel Schneider, presiding =
justice,=20
Over the attorney "Required" provision of the Medical =
Malpractice Act=20
and the RULES of the court especially what the court calls summary =
judgment,=20
that is slowly but surely headed for the U.S. Supreme Court. Do you =
realize that=20
an ordinary Albuquerque High and TVI School Graduate, has not only =
challenged=20
the District Court system, he has fought a fine fight "PRO SE" =
against=20
a powerful attorney establishment, getting Justice Schneider to declare =
the=20
"Attorney Provision of the Act" unconstitutional!

All either physician has to do is provide proof =
positive to=20
this court, plaintiff and the media that shows that either one of these=20
physicians bothered to do the bare minimum of medical and lab test, EMG =
test, in=20
Feb. 1995 and dates thereafter that they say supports their diagnosis of =
LGMD=20
and total disability that plaintiff can present to social security, the =
DDU and=20
the court and say see, I do have LGMD and am totally disabled and am =
legally=20
entitled to total disability benefits from social security for the rest =
of my=20
life and you can’t take it away or demand pay back. ITS THAT =
SIMPLE. Give=20
me proof that Dr. Gregg ever bothered to periodically re-evaluate my =
medical=20
condition despite several DDU, social security re-determinations that he =
was the=20
only doctor. That support the years of pain and suffering, hospital =
stays,=20
medicines, brain seizures, congestive heart failures, lost of home, =
wife,=20
potential. Please asked the doctors…

I asks this news organization to please at least go =
to the=20
court house and look up and read these cases records and especially all =
the=20
evidence placed before the judge and please present this case publicly =
to the=20
people so that the attorneys can not bury it under a pretense of =
innocence and=20
court rule. I am fighting an uphill battle that has grown very difficult =
to=20
fight. I ask the ordinary people out there who are seeking equal justice =
under=20
the law to Help. Medical experts and documents cost thousands. I am at =
my roads=20
end. Without your financial support the doctors will win by default and =
no=20
money.

Sincerely your,

Frank T. McMurtrey

The first mobile antennas I ever tried and used were bugcatchers. So everythng else I've tried is pretty much compared with them. They are a hard act to follow. I did pretty much match the bugcatcher performance with my "plastic bugcatcher" which is a modified hamstick, but with a bigger "bugcatcher sized" coil. But I really consider it a bugcatcher still in design. It's just lighter and made mainly of plastic. I have a friend who had a hustler setup on his car last summer. I had the "plastic bugcatcher".We both ran 100 watts on 75m. He had trouble even being heard clearly though the static. I was in the clear, no problem at all. And we were sitting about 10 ft apart out in the boonies. I don't know the db difference, but it was quite a bit. And I blame it on the hustler coil. I have one that came with a hustler vertical. I tested it, and tried with a mobile mast etc. It was terrible in comparison to a bug coil, or even my homemade ones. :< MK

I may be misinterpreting this as a statement that wire loss can't be
included in an NEC-4 model. It can. It's done by use of the LD 'card'.
NEC-2 also has this capability.

Neither of these is obvious to me. A dipole whose length is the less than or equal to the diameter of the loop will have a smaller conductor resistance than the loop, yet it can be contained within the loop's area. And would you please be so kind as to elaborate on the reasoning that leads to the conclusion that the radiation resistance of any enclosed shape has to be less than that of the loop?

Roy:

My statements were based on modeling wires with no ohmic losses modeled. In
which case, directivity and gain are equal.

ERP isn't in common use in the amateur community, at least for HF antennas, so I went to the IEEE definition, which I believe also represents common use. The IEEE refers it to a half wave dipole, so this means that Chip's antenna has 11 dB gain relative to a dipole. According to Lawson(*), you can't get this kind of gain even with a six element Yagi on a 1.5 wavelength boom.

What kind of antenna are you using that gives you this kind of gain? Some kind of fractal? How large is it?

Roy Lewallen, W7EL

Hi Steve,

Yes, include me in your distribution.

However, as to your conclusion above. By parts it makes sense, but it lacks a basic unifying statement; that, or at least for myself, I need it expressed perhaps at slightly greater length or in a different manner.

As a competitive design, unfortunately, you miss the small picture. It only takes tenths of a dB to bridge that microscopic gulf that separates your dog from the pillar of antenna design. ;-)

All praise that lofty gift and forever humble yourself in the presence of the fractal solution. (Its almost time for me to re-post the adventures of our fractal monk, lil grasshoppa).

2072. Re: will lightning explode storage battery?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-15 00:00:00 UTC
From: John Passaneau <jxp16@psu.edu>
Message-ID: <8ptu3t$u8o@r02n01.cac.psu.edu>
Source record: 180691

Hi Richard:

I have seen one. The battery that backed up our packet node here exploded after a lighting strike. It blew bits of the battery case all over our mountain top shack. And the acid stained the floor. Our take on what happened was the lighting caused a steam explosion in the battery by vaporizing the water in the battery.

Roy, is it obvious we are considering only loops, such as magloops, (which may be cut into to make a feedpoint) which enclose an area in square metres or square feet ? A straight dipole encloses neither an area nor has any volume. It does not belong to the class of antennas within which comparisons may be made.

The radiation resistance of small loops, regardless of shape, is proportional to the square of the area enclosed. You can use Eznec to demonstrate this. Construct a lossless square loop with the ends almost touching, say 1 mm apart, half way along one side. Cut into it and feed it opposite the almost touching ends. We have dipole bent into the form of a square. Record feedpoint resistive component vs frequency and note relationship. Reducing frequency, of course, is same as decreasing loop perimeter in the same proportion and keeping the frequency constant, and is much more convenient to do with Eznec.

Anyway, every elementary text book including Terman tells the same story. I thought everybody knew this.

(The radiation pattern of a small loop isolated from ground is also very interesting).

In the present context the radiation resistance is the distributed value as is the conductor resistance. It can, of course, be transformed to any feedpoint.

It is necessary only to show that for a given length of conductor the area enclosed is a maximum, and so must be the radiation resistance, when the conductor is formed into a circle. Any other shape of the same perimeter length must have a smaller radiation resistance.

Since the loss resistance is proportional to the length of the perimeter it follows that a full circle antenna has the greatest possible efficiency for a given conductor diameter.

As loop perimeter increases the radiation resistance increases less rapidly. But at least up to the size of 1/2-wavelength perimeter the circular shape always wins the efficiency stakes. A hexagon is hardly any differerent. A square is not far behind. A fractal-ized loop I know not its shape. But one thing for certain it cannot be so efficient as the circle or square which encloses it. Or if

it encloses the same area its radiation resistance will be
the same but its perimeter and hence loss resistance must be
greater.

On the other hand, for a given perimeter and conductor
diameter there's hardly anything to choose between the whole
pack of 'em in terms of dB.

My Ford Ranger has ports with rubber plugs under the seats in the Cab.
I also found no good firewall places, so I went under the cab. Had to
remove a seat to run the cables under the carpet easily.

Richard:

Darn! I guess it's going to have to be the dipoles, then. The fractal
will be too large for my location, and if it's directional, it'd have
to be on a 3D rotatable tower of some sort in order to get the
directivity to point the "beam" where you want it.

Maybe when I have my own place I'll be able to put up a tower and try
it out, but for now, the hidden dipoles are going to have to do.

Thanks again for the info and your time!

73's and good DX!

Leading Phoenix, Arizona based company is hiring 20 Senior RF Engineers for full time positions.

The company is willing to relocate candidates but, will give a preference for Phoenix, Arizona based candidates.

Please, forward your resume with contact information for consideration to davemoen@mac.com

Will forward the job descriptions ASAP, as these positions just opened today the job descriptions will not be complete until later this afternoon.

John Passaneau wrote:
"I have seen one."

If hit by lightning, it is easy to anticipate a battery explosion.
Batteries are usually easy to protect from lightning exposure.

A battery`s charge/drain path can contain a series inductance which
negates instantaneous current change and can contain shunt capacitances
which disallow an instantaneous voltage change. Breakdown devices then
have ample time to act, clamping the voltage to a safe value and
bypassing excess current around the batteries and connected equipment.

Best regards, Richard Harrison, KB5WZI

W9INN antennas are very good. I bought one from Bill. Very well made,
great performance.

He is in Chicago area. Very (I mean very) small add in CQ and QST each month
near the back.

(I have not financial relationship with him other than he cashed my check for
his product).

He was on disability leave so he may be backed up but I just got my antenna
last week (ordered in early July). Give him a call; can't say enough.

How did I find him? I did the same post several months ago and many people
came back and recommended W9INN.

This is basically a statement of the small loop approximation, which (INCORRECTLY) says that the radiation resistance of a small loop depends solely on the enclosed area and is thus not a geometry-dependent quantity.

For almost 5 years now, this small loop approximation has been shown to be wrong, through the work of Cohen and Hohlfeld. In fact, the RADIATION RESISTANCE of MI2 is HIGHER than that of the same sized small loop conventional wire loop.

This arises because MI2 incorporates 2 current max's, whereas the small loop has only one. The best that can be done with the small loop is to get a uniform current distribution.

Incidentally, I find it disturbing that I am getting 'hate' mail now (again! What is it with some of you guys!!) accusing me of being wrong; committing fraud; and so on, because of the fellow from Cushcraft's supposed results.

I haven't read his posts and won't, but I have been told he claims that any ARBITRARY origin-symmetric loop structure gives the same radiation resistance, resonance, and efficiency as MI2.

After the Open House I'll spend a minute or two giving just one counterexample that throws that bogus statement apart.

I will say that I spent a good part of a couple of years in the early 90's exploring just this issue of finding the best performing antenna for a given wire length in a small form factor.

He is clearly wrong. For anyone to say this, they cannot have a good handle on understanding:

* mutual coupling;
* resonance;
* ohmic loss;
* radiation resistance;
* field strength.

Using words like 'directivity' and 'impedance' are cop outs that deliberately avoid issues such as field strength and efficiency. I have no idea why someone who claims to do antenna work would use NEC4 to get directivity rather than field strength, or quote an impedance rather than a radiation resistance (at the current max).

Field strength is the salient observable.

I remind everyone that this Cushcraft person formally told us that he had a 20 turn spiral that had better 'directivity' than MI2. Of course it has a far lower field strength because it uses 4 to 5 times the amount of wire!

Gee! Tiny phased arrays have OODLES of directivity and boy do they stink!

Please: no more hate mail. It will get you into trouble.

Hi All,

Another phrase courtesy of Oscar Wilde:

"It is a much cleverer thing to talk nonsense than to listen to it."

OR judging by the quality of some postings:

"There is only one thing in the world worse than being talked about,
and that is not being talked about."

OK OK enough, to finish where we began:

"Education is an admirable thing, but it is as well to remember that
nothing that is worth knowing can be taught."

\
a single quad element is a useful wideband antenna. the main lobe "on axis"
gain exceeds that of a dipole over the range of about 0.5 L to about 1.8L,
where L is the noinal or design wavelength, ie, a wire which is one
wavelength long. Of course, to use this, you must hae a low loss
transmission line, open wire, ladder line or teflon coax, plus an antenna
tuner. If you don't mind the pattern change, the upper range goes to several
times the nominal; L.
Ive used a 20 Meter loop on the bands 12-30 meters many times.

Message-ID: <39C2A863.6552C0F1@eznec.com>
Source record: 180707

Guess I'm being one of those nit-pickers. First, there was nothing in your statement (which I thought was directed largely at fractal antennas, some of which are closed and some not) which restricted it to loops. So it wasn't apparent to me that you were restricting the statement to closed loops. I also made the mistake of taking your statement about conductor loss literally. A smaller loop is "contained within its circular area", yet has smaller wire resistance. Apparently you meant that a round loop has the smallest conductor resistance of any loop containing the same area, which of course is true from basic geometric considerations. It's just not what you said.

About the radiation resistance claim. The only Terman book I have is _Radio Engineering_, Fourth Edition, and I couldn't find any discussion of small loop antennas in it, although I might have missed it. Kraus devotes a whole chapter to loops in _Antennas_. In it, he shows that a small circular loop and small square loop, each with uniform current, have the same pattern and radiation resistance provided they enclose the same area. I can't find where he applies the generalization to any shape loop as you have. The requirement for this equality between circular and square loops also depends on uniform current distribution, an assumption which begins becoming invalid at very roughly a quarter wave perimiter length. It's not hard to imagine a non-symmetrical loop shape like, say, a keyhole, which doesn't have uniform current distribution, so wouldn't fit the requirements (besides not being round or square). The relationship between the field from this and from a circular loop might depend in quite a different fashion on their enclosed areas. So although circular and square loops with uniform current have the same field strength and shape and same radiation resistance provided they have the same area, I haven't seen any evidence that this applies to any enclosed shape whatsoever. It isn't obvious to me that a fractal antenna, even though it would fit within a small loop, would necessarily have a uniform current distribution. But it isn't square or circular, either, so I don't believe we can make the assumption that its field will be the same as a circular loop enclosing the same area. If you're aware of an analysis that shows that the area rule is independent of shape, I'd appreciate knowing what it is so I could look it up.

It's easy to forget the conditions under which well-known rules are valid -- I got caught by this myself the other day.

Don't interpret this as a claim that a small loop can't be the most efficient antenna of its enclosed area. I just don't think it's "obvious" that it is, and don't think you've demonstrated that it is.

Roy Lewallen, W7EL

OK Tom (and group), I'm learning a lot here, ...

1. What is a beverage antenna?
2. In lay terms, why does it work so well to the ground
3. What effect does his resistor in the end have (if any)
4. Does this work for transmission too or better for just reception?
For personal emails please remove the obvious

Thanks!
Wayne

2093. FracTriad

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-15 00:00:00 UTC
From: Richard Clark <rwclark@rwclark.seanet.com>
Message-ID: <TdHCOViyKfHiigEBuXtBWEqg29bs@4ax.com>
Source record: 180712

Hello Dear Readers of the fractal Persuasion,

FracTriad is three offerings derived from one main fractal design. That main fractal design, a Koch second iteration triadic, is supported by three insulated guys that attach near the elevated feedpoint and travel downward to ground at an angle of 45 degrees. This basic construction is applied as three variations at two elevations. The simplest design variation, the Fractalope, is complete in its data and the remaining designs have "gaps." I will be closing up those gaps this weekend.

Your mission, should you care to accept it, is to construct the antenna:
1. For each guy, measure out from the feed point end as indicated in the Design Details and attach a tie-wrap (there are 16 - 17 spread over the three guys);
2. On the ground (never attempt to do this above ground) tie off the three guys to a common anchor and then spread them to three remote anchors that create a span of 45 degrees overall (the pictures will reveal all);
3. At the feed point end connect a 14.3 meter length of wire to your 1:1 Current BALUN. The BALUN should be mounted very near (if not at - or serve as) the guy's common attachment;
4. Pass the unconnected end through the loops already installed in step 1.
5. What follows has several options. Basically if you can establish the 45 degree spread and tension on all guys, you only need to attach the far end at the last tie-wrap. Or you can tie-wrap all 16 - 17 points. The advantage of the single attachment is it may give you flexibility if guy anchoring is problematic.

The five steps above are the not the complete drill, but they are the common steps for which ever design variation you decide to choose.

qsl.net's ftp server still appears to be down so I have posted the new pages at:
http://www.seanet.com/~rwclark/fractal/
and follow the links to "Practical Designs" (the first link at the top of the next page).

This is a work in progress. Incomplete. Redundant. Perhaps an error ;-)

Can we say that even though it reduces the signal level, it reduces
the noise level even more thus increasing the S/N ratio?

2096. Lightening Rod...aka Tower Installation tips

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-15 00:00:00 UTC
From: "SteveTheGeek - West Central, IN" <stevethegeek@newmail.net>
Message-ID: <ss5rdmn8h3t77@corp.supernews.com>
Source record: 180715

I'm into the planning stage of building a tower approx 100-120' high. Why so high you say?? I live in a woods and the average tree height around my property is 90'.

The biggest reason why I need such height is not because of ham radio (WHAT!?).

Granted, having that height would be very, very, excellent for ham, however I need the height for my DDS dish. The dish is unable to obtain the satellite signal ANYWHERE on my property at or near ground level. I just have too many tall SW trees...btw, I could cut a path but my half would kill me. SO my only other alternative is UP!!

Because that tower will protrude above the average treetop line, I am really concerned about my tower becoming a lightening rod. I looking for info about proper tower installation, grounding, etc.

This much I know: I am about 150' from the nearest powerlines and the tower will be approx 30' from my house. I will be able to hinge the tower for on-ground maintenance, but the only direction available (due to the trees) will be towards the powerlines.

Any suggestions? I could use ALOT of them. Never erected a tower before so this is a first for me..thx

Mark:

Thanks for the ideas, and the information.

The whole point of this is for me to learn something. I'm not going to learn anything by trimming a bought antenna. I already know how to do that. ::grin:: As evidence, the coil loaded vertical dipole I have on the back of my car for 11M. It works well enough, but I need to get it higher, which means I need to get a longer threaded rod to mount it on, and set up some supports. But that's a different post, and a different topic.

I'm not into radio just to talk. The challenge of experimentation, the thrill of getting it right and being able to talk on it, the electronics knowledge gained, being legal to work on my own sets, etc, are the major reasons for my desire to become a HAM, and to build my own antenna.

I live in a basement apartment in a 2 story (3 with the basement) building. Right outside the "fire escape" window in the livingroom is a rather large pine tree. I was going to use this tree to "hide" my antenna from the landlord. He knows I'm going to be putting something up soon, and he knows I'm going to do my best to hide it as best I can. In the pine tree (a very large blue spruce) seems to be the best location, to me. I'm trying to decide between a pair of vertical dipoles (one for 10, and one for 11) or a fractal type, based upon real data, which Richard was kind enough to provide, and built by myself.

Dipoles are easy, now. I've built four of them. No challenge there. But the Fractal, which may indeed be broadbanded enough for my purposes, made out of steel electrical conduit, brazed together, and properly fed, and hung in the tree, might be another solution. The tree is, by my estimation, about 45 feet tall. I can probably get an antenna up about 40 feet in the tree. The bottom of the tree leaves another 4 or 5 feet showing, so my total length for an antenna is somewhere close to 35 feet. The dipoles will fit nicely in that space, but will the fractal? That data I haven't gotten yet.

At any rate, I'm encouraged by this openness and information. Hopefully I'll get this code thing licked, I'll get my desired vanity call, and you'll hear me calling CQ on 10m USB soon.

73's and good DX!

I have never heard of using radials with a loop/quad? For that matter, I have never heard of them being used with any balanced antenna--loop, dipole, yagi, quad, etc. My understanding is that radials form an electrical image plane that compensates for the "missing" half of a vertical monopole, somewhere for the current to travel on the other half of the cycle. Why would you need this with a dipole, or a loop? What purpose would it serve?

Wow...

Finally Dr. Cohen seems to be posting some quantitative information on this NG now!

Sadly it is only in response to the efforts of Steve VE3SRB to actually present some quantative analysis/simulation results on a (fractal?) antenna.

Dr. Cohen's post seems to have a very "defensive" tone, I wonder why?

Steve, thanks for your modelling efforts, I for one, and I assume many of us NG participants appreciate your unselfish efforts in this regard. We have grown tired of the bafflegab, unprofessional and unscholarly approach to information sharing exhibited here by certain factions of the antenna design community.

Nuff said...

> Randall D DuCharme (KD5IZI)

Hi Randall and all,

The question you ask about making a 160/80m vertical using the same principal as the R7 Would be difficult to acheive on 160 and 80m , the R7 uses electrical 1/2 wave and the short radials are not true radials at all but what is know as decoupling stubs. on 160 for instance you'd have to have a vertical (full 1/2 wave would be 256 or so feet tall) and even then you'd still want a good ground plan unless you could get the base up about 1/4 wave (130 or so feet) above ground. Your best bet is to bite the bullet and laydown as many radials as you can. (note : you can shorten the vertical in height by using some form of loading , Coil, top hat etc. but it is a compromise . Antennas (for these lowbands most generally are a compromise of some sort) the trick is to get the best efficency and low angle take off, while putting the most of
your transmitting power to the either. And use a good receiving antenna.
Not to say that what you want can't be done. you'll just have to decide what your willing to trade off, to do it.

The studies extended significantly past animal studies, of course. The level at which these types of problems was observed was 4 w/kG. The ultimate standard was, however, set at an SAR of one tenth of that level for controlled/occupational exposure and one fiftieth of that level for the unconcontrolled/general-public level.

See

IF I was running a KW, then my far field ERP would be close to 12,000 watts.

Now: IF you were louder "anywhere" than me, BY 20 dB, then your ERP would be 1,200,000 watts.

That's 1,200,000 watts.!!!

Chuck--have you checked the minimum compliance distance on 10M for 1,200,000 ERP?

It sure sounds like a visit by the FCC would help you check your numbers properly, or reduce your ERP to acceptable levels.

I think I did that once -- just laid it on the ground. It didn't work very well.
A buddy of mine - WB5LOZ use to run phone patches from Vietnam using a 15 meter
dipole strung between a chain link fence and eve of a roof. All less then 10 feet
off the ground - and did quite well. I never understood that either.

This is a good example of how all perspectives vary.

Hamstick owners often consider their antennas good enuf.
Hustler and Hamstick owners know the Hustler is better.
People who have compared a Bugcatcher to a Hustler know the Bugcatcher
is better.

>Chip N1IR

Having done designs for Heath, I'm familiar with the SB-220.

The SB-220 is capable of slightly more than a kilowatt out on ten
meters running on a 120 volt power source, or a 240 volt source.
Source voltage makes no difference, as long as the house has decent
wiring.

But then Chip should know that, since he is a "PhD".

The actual CW output was designed to be around 600 watts, but the amp
will do about twice that amount.

Beverages work OK laying right on the ground. Certainly a little
height is better, but most soils are lossy enough they work OK on
ground.

The main problem with laying the wire directly on the ground is the
attenuation in the wire increases. Who cares if the signal is -20dB
or -25 dB? Not anyone with a sensitive receiver!

>de Will KD7BFX

Hi Will,

The mental picture that a radial system provides an "image antenna"
is incorrect. It's a common mistake, even QST made that error in a
"Ask the Doctor" column.

The radials can do two things.

1.) The provide a second terminal for the feedline to "push" against.

2.) They "shield" the lossy dirt below the antenna from the strong
fields the antenna produces.

Because of effect number 2, they help the performance of any antenna
close to earth in terms of the wavelength and the antenna size.

>

This is reasonable and good advise, although not always practical because it is sometimes difficult to get all segments exactly the same length. Looking at your papers published in Comm Quart, it appears that you used 3 segments/wire in some cases and 4 wires/segment in some cases.

In most cases, I am more concerned about how the models react to changes in wire diameter.

>
> IMHO, anyone who uses NEC4 for gain values only-- does not incorporate
ohmic
> loss-- and uses uniform segment numbers per WIRE (even though wires are of
> different lengths) is not an experienced user of NEC4 ,and their results

> be taken with much credibility.
>

It has been my opinion that the NEC "gain" numbers are really an indication of directivity, since radiation efficiency is presented as 100%. The radiation efficiency of the antenna will be a function of the ohmic losses in the wire. However, if you are comparing two antennas with similar resonant resistances and exactly the same wire length and wire diameter, this point becomes irrelevant.

For the most part I try to use uniform segment lengths over the wire structure but it is not always possible to get exact segment lengths everywhere. In many cases, I use uniform segment numbers per wire and get acceptable results. If I am concerned about the results, I usually increase the segment density.

Just and FYI - As for credibility and experience, I have been running MOM models on antennas since about 1983.

I ran my NEC4 model of the MI2 loop with 3 segments/wire throughout the structure. The results were consistent with those presented in your papers

and I was not concerned about this issue. So that it is not an issue in future posts, I will adjust the number of segments/wire to match those indicated in your papers.

> All my results have been published. Readers are cautioned that incorrect
> observable values and references are not my responsibility and indicate a lack
> of scholarly responsibility on the part of the poster.
>
>

If this is an issue, the whole matter of model discrepancy could be resolved with your posting the EZNEC file for the MI2 Loop.

Thanks,

Steve, VE9SRB

>MEGA amps, both at the same time! This will kill any electrial equipment:
>period, if it dosen't set your house on fire.

Except when it doesn't. It turns out that a good many lightning strikes cause little or no damage to the equipment that is struck. The effects are highly variable: my guess is that damage is largely a function of the duration of the high voltage and current.

>On a lower level, the high electric fields stand a good chance of doing
>your computer gear serious damage. Unpluggging it all, including from the
>telephone line, will minimise the risk.

Well, both modems and computer power supplies get damaged, but for the most part they're surprisingly sturdy compared with other appliances in your home. Both have considerable built-in circuitry to limit overvoltages.

>If your backup systems involve car batteries, as do most, I commend you for
>your providence! And I assure you, that If you have a lightning strike of
>sufficient vigour to explode a lead-acid battery, that will be the least of
>your problems!

I agree, but there's always a certain amount of luck involved here. If, for example, there was a bit of hydrogen in the battery and a minor arc developed from even an indirect strike, it's possible that there could be some damage, though it's more likely that the vents in the battery case would handle the pressure increase.

>> Let's say I have a 12 volt car battery hooked indirectly to house current
>by

>> tc. --- or any other situation where lightning might get to a car
>battery...
>> upon a hit is my house at risk of an exploding car battery... acid/fire
>damage?

It's unlikely that even an exploded battery would start a fire, though it wouldn't improve your interior decoration much. Over their 120 year history, lightning hasn't been considered much of a threat to lead-acid storage batteries.

I'm having very good results with the Alpha Delta DX-CC: Japan, Alaska, Argentina, Norway, Italy on 200w or less.
For the sake of experimentation, I am getting set to put up another dipole (42' by 94 ', a 4:1 balun fed with coax) to see what happens - I've been told that works pretty well, too. The DX-CC tunes fine with the xcvr's built-in tuner (Icom 775DSP) ,even on 17M (although just barely). I'm shopping for an external tuner for the other antenna.

>That's 1,200,000 watts.!!!

I went throiugh the same exercise with a fellow using a poor antenna.
He accused me of running big power, because I beat him by 20-30 dB.

In reality, he had an antenna performance shortfall he wouldn't admit,
plus many S meters were showing a bit more difference than actually
occured.

It's not unusual for a well-engineered station like Chucks to beat a
tinker-toy station like yours by 20 dB.

>It sure sounds like a visit by the FCC would help you check your numbers
>properly, or reduce your ERP to acceptable levels.
>73
>Chip N1IR

Here's how Chip's call would go......

"Hello FCC"

"FCC , this is Nathen Cohen PhD. Chuck is beating my Fractal antenna
on ten meters and I want you to drive over there and check his power.
According to my math, he is running over a million watts ERP."

"(snicker) Dr. Cohen ehhh? The guy on Rec dot radio dot amateur dot
antenna? The one who uses 10 log for voltage decibels?"

"Yes, that's me. I demand you investigate him"

"We'll get right on it Doctor Cohen (chuckle)" "click" huummmmmmmmmmm

The next action taken by the FCC will be hiring a new engineer, to
replace the one who mysteriously died laughing.

I may be wrong, but I think the fractal antenna being discussed
is directional, unlike an ordinary 1/4WL vertical, so some means
of rotating it may be necessary for all-directional coverage.

2125. UKW AND Dipol or YAGI

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-15 00:00:00 UTC
From: Robert Bukowski <robert.bukowski@gmx.at>
Message-ID: <39C2258F.1F913ABB@gmx.at>
Source record: 180813

I have written about my problem in this NG about 3 weeks ago and
it is not solved up to now. Now to my problem:
I am living in Vienna/Austria/EUROPE in the first district. In the house

where I live there is installed a common antenna-equipment for radio
(UKW),
TV (1xVHF, 2x UHF) and two satellite-dishes (Satellites ASTRA and
HOTBORD).
To the switch-boxes (SPAUN, Made in Germany) are connected ten
customers,
whereby only one cable is leading to each participant. I do explain this
in such a
depth because I don't know if this is usual in this way in other
countries especially
in USA.
All the satellite and TV reception is excellent but there is a problem
with UKW.
I do want to receive a radio-station, FUN-Radio
(http://www.funradio.sk), which
is located about 40 miles away in Bratislava/Slovakia. Thus I have
installed an
UKW-Yagi consisting of 7 elements looking that direction. The antenna is
mounted
horizontally, whereas FUN-Radio is transmitting vertically. With that
antenna I get
a signal of 46 dB and the local radios have a signal of 78 dB. That 78
dB are too strong
for the other signals, so I have to lower the complete UKW-Signal bay 6
dB. By doing
this FUN-Radio gets noisy.
At the same time another radio-station, ï¿½3 (66dB), which transmitts in
an angle of about 120ï¿½
away from Bratislava has some sizzling.
My idea would be now to replace the horizontally YAGI by a simple
vertically dipol mounted
on a boom and still looking at Bratislava. This should strengthen the
signal by 15 dB and the
sizzling-problem should also be solved, because there shouldn't be the
problem with different
incoming phasis because of the vertically orientation of the dipol.
However some experts are saying that the polarization should have nearly
no effect in such
a distance to the transmitter.
Please tell me your opinions about it because experimenting would be too

expensive to me
as I am not willing to make the installation by myself because I do not
dare to got out on
the shelter by myself.
Thx
Robert

Steve and Frac,

Isn't this much ado about nothing ?

From fundamental principles, it should be obvious a circular loop with a perimeter of 1/2-wavelength has a radiation resistance greater than, and a conductor resistance less than any shape, certainly a fractal shape, which may be contained within its circular area. Consequently the simple loop has the highest efficiency of all possible shapes having the same length of conductor. (All antennas having the same conductor diameter).

There comes a series of regular polygons in between circle and square all with the same length of perimeter. All of which will have greater efficiencies than a fractal contained within the same area. And if a fractal has a greater bandwidth it is only because it is less efficient.

SWR versus the completely arbitrary value of 50 ohms is meaningless in the present context. A loop can be matched to a wide variety of impedance lines.

I am using an equilateral triangle, made of wire, on 20M. The apex is up, apex at about 44 feet. Its fed in the middle of the base / bottom. No balun..... I use a quarter wave of 75 ohm coax between the antenna feedpoint and the 50 ohm coax feedline. I can turn this antenna.

It easily outperforms an inverted V with apex also at 44 feet.

I tried feeding it at the corner of the base. It seemed noisier, and I had this vague feeling that it just didn't perform as well overall as feeding in the center of the base. Corner feed is also more cumbersome to rotate. I use this antenna mostly for chasing DX. It is very definitely directional. If you construct something like this, make damn sure you make it so you can rotate it.

MOST fractal antennas * cannot* be modeled in NEC4 because of width/segment length issues. However, the ones that I have published are amenable to NEC modeling, as are many limited iteration fractal wire antennas.

Thus my exhortation withh the $1000 FRACTAL CHALLENGE. Frankly, I will be very interested if any antenna beats the MI2, and if it does, I wonder what kind of fractal it is:-)

Here is the time scale and use of various NECS which I have used:

1994,1995 miniNEC
1995, 1997 NEC2
1997,2000 NEC4

I would estimate I have about a man year or more using NEC in its various forms, although a lot of that was just waiting and thus doing other things. In the early days of slow PC's that included sleeping!.

NEC4 produces a different result than NEC2 because you can model more segments. I ALWAYS oversample the current density, and use UNIFORM segment DENSITY (number of segments per unit length) per wire. NEVER UNIFORM SEGMENT NUMBERS PER WIRE!

IMHO, anyone who uses NEC4 for gain values only-- does not incorporate ohmic loss-- and uses uniform segment numbers per WIRE (even though wires are of different lengths) is not an experienced user of NEC4 ,and their results cannot be taken with much credibility.

I am especially struck by how many NEC users (with no commercial gui's) do NOT incorporate ohmic loss. Why they just don't use EZNEC is beyond me. It's not as if it is overpriced.

(EZ)NEC4 produces models of field strength of about 1.9 dBi ,and well over 90% efficiency for MI2. I have found that inexperienced modeling still affords marginally reasonable approximations: the field strength is off 0.4 dB or so (no biggie) BUT with resonances off by several percent. I consider that a

problem, although others might not.

All my results have been published. Readers are cautioned that incorrect observable values and references are not my responsibility and indicate a lack of scholarly responsibility on the part of the poster.

I'd have to ask Bob Hohlfeld about this; been a long time since I coded and an even longer time since I used FORTRAN.

I can see that you think there is nothing in the code that precludes more NEC2 segments; I don't doubt that.

It would have been more precise if I referred to EZ NEC and EZ NECPro/(4). Perhaps you could kindly guide others on which have segment limits, and so on.

I almost never use EZNEC (as opposed to ENECPro/4) anymore, so perhaps my memory is vague on this. For example: what are the segment limits on EZNECWin?

Thanks!

Hey fracky...
Huh?
Have you ever put up a beverage....or even modeled a wave antenna?
Extract that foot from your mouth and think before replying...
You can even lay the wire on the ground and it will work very well,
ground contours and all.....

Terry:
Try it. Test the length of wire without even bothering to terminate it.
That will give you some idea quickly how well it may work. Just lay it on
the ground if you can't support it at 5 - 10 ft. The height will just give
you
more (5 - 10 dB) input to your receiver, but as others have correctly
stated,
more than 10 ft or so up, it will start behaving like a longwire and the low
angle
response to DX drops. I speak from 30+ years of experience...no phd...

That is wrong--at least on the last two statements.

Furthermore, if you are suggesting I am running 1 KW, can you explain how this is physically possible? I got the SB 220 back up this Summer, but I would like you to share what your sense is of how much power one can obtain, under ideal conditions, for output power on an SB220 on 10M, running on a 120V line.

Are you familiar with the unit, or is your knowledge base limited to amplifiers with much higher outputs?

>
> Many thanks in advance.

The radials on the R7 a counterpoise to help decouple the feedline from the antenna. So that setup would only work if you duped the whole antenna and resized for 160/80. The R7 is a physically short 1/2 wave design and as such requires no radials to operate. But that still doesn't account for ground losses if the antenna in mounted low to the earth. ON 160/80 you will likely be using a 1/4 wave etc antenna that will require radials both for proper operation to complete the lower half of the antenna, but also to reduce ground losses. I'd just string out as much as possible. If you use only 4-8 radials you might consider keeping them up off the ground a bit. This will help, but might be a problem if people will trip over them. It's just one of those things you have to decide how hard core you want to get. 4-8 radials will likely do ok. But 60 will do a good bit better. According to some modeling of verticals I've been doing, on a ground mounted 1/4 vertical, seems that each time you double the amount of radials, you gain appx .4 +- db. But thats just an appx number. I just ran a vertical thru the elnec program, and over good "G" ground, the 1/4 vert with 4 radials showed 0.255 dbi gain at a maximum at 27 degrees. With 60 radials I show 2.710 dbi gain at a max at 24 degrees. Pretty close to effectively doubling your power by adding the extra wire, and the angle of max radiation lowers a tad. Usually only the hard core vertical nuts go to the trouble of 60 or more radials. But I think it's worth it if you want the most performance. Just lay out what you can. I don't know if you have the room, but you might consider an Inverted L. Easy to string up and will work fairly well. I'm also in the process of deciding on a 160 vertical. I have a 40-45 ft tree I think I'm going to use for the support for the radiator. I was thinking of a loading scheme, but after thinkin it over, I think

I'll avoid loading altogether and use a inv L or a T vert. I already
have a 160 Z dipole for close stuff, but I want a long haul antenna. MK

Gee....who said put it up more than 10 feet high on 160M?

I speak from 30+ years of experience...no phd...
>
>73,
>Chuck...K1KW

Unfortunately you are incorrect in your generalizations. Depending on the
ground type and uniformity, placing the wire on the ground will yield some to
no retarded wave. The gain of the antenna will also drop severly, usually 20 db
or more, not 5 or 10dB.

Anyway, I think Terry SHOULD try your suggestion and then compare with the
antenn up in the air.

> a tuner.

I'd just tune for one band or the other and use a tuner on the band not resonant. The loss from the tuner will be low as you are not looking at a really bad mismatch. I'd just find a good CB antenna, and use it for both bands. I'd tune it for the band I used the most, or possibly had a use for higher power. So if you ran 10m 75% of the time, and 11m 25%, I'd cut it for 10m, and slap a tuner inline for 11m. Heck, with these low power 4w AM/12w ssb radios, you might get away with a fairly high SWR.

> I prefer SSB as my mode of operation, as I've stated before, and I'm
> not 100% sure which frequencies on 10M are acceptable for SSB, and

> help narrow down my choices.

If I remember right AM starts about 29 mhz. Most SSB use is from 28.300 up to 28.9?? or so I guess. The tech pluses are good from 28.300 to 28.500 with 200w output max. But this is not a novice sub band, as is the lower novice CW/data portion. So generals up can run up to 1500w anywhere except the CW novice subband. Everyone must run 200w in a novice subband.

> I consider a "safe" swr to be anything around 2.5:1 or lower. Maybe a
> dipole set for the center of my desired transmit range would be the
> better choice, using a tuner where necessary at the ends?

It would be fine. But I prefer a good vertical for 10 m in general. The local coverage much better for one thing. MK

>
>73,
>Chip N1IR

Just spent a few minutes checking the DXCC tally with the 10M FQY.

Since August 1998, in a generally casual manner, I have worked 289 DXCC countries with the 10M FQY. Basically, if it shows up on packet cluster, and I can get on, I work it:-)

My 310 count was down at 298 (I believe) when I got on with the 10M FQY 2 years ago.

So basically I've worked about a dozen new 10M DXCC countries with the antenna. I believe I am at 345 or 346 worked DXCC overall (I received #1 Honor Roll in 1995).

For a description and operating performance details, see the ham page on

http://www.fractenna.com

Also, I have decided, for the first time in 11 years, to get on a contest. I plan, at this point, to get on the 10M contest in December--with full intent to show how operating skills and the proper antenna--even in a small and compact

form at low height--do super well.

Frac, it was certainly common knowledge in ancient Greece, 2400 years ago, that ALL approximations are incorrect and wrong.

8000? years back it is possible the inventors of the circular wheel, in Ur in present day Iraq, in the far more ancient land of two rivers, were aware that 22/7 did not equal Pi. It still doesn't. But its only 0.04 % in error. And just look where that has landed them !

One way you could go is to use loading coils at the feedpoint feeding
each leg. This would be the same method as feeding a 5/8 gp except that
use are running horizontal and have the same thing on the other side.
For 17m you would probably need about 15-20 turns on a 1.5-2 inch form.
But just guessing , you can trim for best match. You may also be able to
use a piece of 75 ohm coax as a transformer. Also I think Cecil stated a
method once that used a piece of ladder line as a transformer. Dunno,
the coils may be about as easy as anything. They would be fairly small.

Well, actually either one could be "correct" with a certain design. The 16 inch spacing pretty close to .20 WL, and very common. The longer 20 inch ".25Wl" spacing sounds like maybe they are trying to get a bit more gain. I'd go with whatever is easiest to build, but I'd stick with a single design. Don't mix and match unless you are very careful. I'd use a modeling program to double check things if I did that. The 16 inch spacing sounds fine to me for an average use yagi. MK

Chip- If the house wiring is adequate, there should be little or no
difference in the 120-240 options. Have you measured the voltage at the
AC input line when you are in operation?

THis is NOT a facetious question- if the wire in the house is dropping
voltage to your amp- there is the possibility that you are overheating a
mains (romex?) wiire within your structure. This could be dangerous.

Got the same radio. Use it at home and in the car.

Here is what I did at home. I am about 20 miles from one repeater and 25 from another. I get full quieting in with 50 watts.

I bought a small larsen 2m/440 antenna (NMO mount) and a mag mount. The antenna is about 18" tall with a buldge in the middle (not sure what it does). It looks like a big cell phone antenna.

I mounted the mag mount on a safe in my attic. You could mount it onto A/C ducts or even a cookie sheet on the floor. A little RG-8X and I am on the air, full quieting to the repeater.

Total antenna setup: about $40. No need for a fancy antenna. SWR, measured with an MFJ analyzer is less than 2:1 on the repeater frequencies, and is usually 1.5:1.

Unless you are running an SWR of 1:1 on the 450 ohm feedline, you
will NEVER see 450 ohms at the transmitter. I doubt that you need
a 9:1 balun. I feed my 130ft dipole with 450 ohm ladder-line and
I use a 1:1 balun/choke.

With a 17m EDZ up at 40ft, EZNEC sez it should be 64.5ft long and fed
with 9.3ft of 450 ohm ladder-line for a 50 ohm SWR of 1.4:1. I wouldn't
lay it on the roof. Can you suspend it above the roof? Adjust the 9.3ft
series section length until you get minimum SWR.

In general, an EDZ is 1170/freq and the series matching section (series
transformer) is about 0.185 wavelength (including velocity factor).

The coils I've made in the past were made from real stiff wire, #12 solid house wire, and self supporting as long as both ends are held in place. But you could wind them on PVC. That wouldn't be a problem, and actually could work fairly well as you could drill holes in the ends of the PVC to attach the wires. Would be strong. The ladder line method will work also, except that you need to keep the LL section fairly straight and in the clear. According to Cecils post would be 9.3 ft long. Normally wouldn't be a problem as most antennas highee than that. But the coil method kinda handy as all coax to the feedpoint, and little effect from rain. MK

I think you are right. Moving from the feed point each trap serves to terminate the antenna when operating in the band of the trap. Thus when feeding a ten meter signal the two ten meter traps effectively make the signal see only the portion of the antenna to the coil/traps. On 20 meters the 20 traps do the same thing, and the 10 meter traps typical function as inductive loading which allows the trapped dipole to be physically shorter then its apparent electrical length. Thus when operating on the 80 meter band, the 10, 15, 20, and 40 meter traps serve as inductive coils allowing the over all physical length to be shorter.

If you adjust the operating frequency of the antenna on any band other then 80 meters you would have to consider its effect on the lower bands. For example adjusting the operating frequency of 40 meters would also effect the 80 meter portion of the antenna.

Just my thoughts. I could be wrong - I am just a social scientist. Ham radio is just a hobby for me.

I listened to LW stations all over Europe during the years I lived there on the car radio using only the radio`s short whip.

You will probably have good results with a wire pointed in the general direction of the stations if it is as long and as high as you can make it.

Otherwise, an active (amplified) whip located in the most noise-free location found on your property is a good bet. You need a shielded or balanced feedline to avoid noise pickup in the vicinity of your receiver.

Best regards, Richard Harrison, KB5WZI

Chip, how much power I get out is another story. Last night I loaded on ten meters, stayed in the low power position and noted 400 watts or there abouts on a MFJ Versa Tuner watt meter. But that was the low power position. When I switch to high power - which is rare - I really don't get much more out. Just a bit over 500 watts on the same meter.

I don't think I have ever seen more then 700 watts on my watt meter - which may explain why I consistently show a lower then expected output.

So, you appear to be doing considerably better then I am.

>On this one, which is on 120v, I can get 850 w IN, tops, on 10M.<

At 60% efficiency, I get 510 Watts CW output. Add in the driver contribution, and that's 610 watts output. Correct for power supply sag between CW and SSB duty cycles and you pick up another 20%--perhaps 730 watts output on voice peaks. Anyone find that an unreasonable assessment for those CW input numbers?

I wonder if anyone has had an experience of the SAGANT ZA-7 end fed half
wave wire antenna for 40m?
I have acquired one recently and seek advice regarding the feed before
trying it.
Maybe a matching quarter wave length of 75 ohm to a 50 ohm feed to the atu?
Any advice gratefully received.
Ray.

That doesn't read right for some reason...

> At 60% efficiency, I get 510 Watts CW output. Add in the driver
contribution,
> and that's 610 watts output.

If you are reading 510 watts out, that would have to already include the
"driver contribution" to the total output.
I don't see how the additional 100 watts can be added after reading 510
watts CW output to make it
610 watts.

Pete

>outages can be tolerated.

We used G line for a 535 foot run up a tower at 7 GHz (TV microwave
relay). It worked fine. We used teflon insulated wire, and it sustained
no ice buildup in winter (ice wouldn't stick to it). This dramatically
reduced the ice loading we normally suffered using waveguide on
towers in the area.

There was some rain attenuation, mainly due to water pooling in
the lower launcher. Rain covers caused greater losses, so we just
drilled some holes and let the water drain through the horns. This
worked much better than using a spatter board, wind loading was
negligible, and it cost very little compared to a 535 foot run of
waveguide.

G line can be bent with negligible increased losses as long as the
radius of bend is 10 wavelengths or more. So wire sway due to wind
isn't a problem. What will cause increased loss is wire supports,
horn covers, etc. Even non-metallic supports cause losses. It is
very sensitive to discontinuities in the dielectric environment. This

makes horizontal runs of G line longer than one span impractical.

Mak,
I have no idea what the input impedance will be, except to
expect it to be higher than 50 ohms. With out knowing a lot
more about how you plan to use it, the surrounding objects, etc,
it's not really possible to guess the input impedance.
A balun won't do much good (Not a balances antenna to start
with).
A second floor 'earth', or ground, isn't the easiest thing
to realize. Dropping various length counterpoises from your
feed line exit point may help. The earth system at ground level
may not be of much use (shouldn't hurt, though).
It's only personal experience, but I've never had much luck
with long wire, or random wire antennas. Too lazy to put in a
good RF 'earth'/ground system is part of the reason...

Paul,
Is there a terminal on the back of the tuner for an external
antenna?
If there is, then you may add an external antenna with not much of a
problem. The longer the antenna, the better the reception (in
general).
Also, the higher the antenna, the better. I would start by using an
antenna of what ever length of wire you happen to have handy. If it
improves reception, you might try adding more wire. For a receive
only
antenna, the size of wire makes little difference. As long as it is
'large' enough to hold it's own weight with out breaking, it's large
enough.

Joe,
The other suggestions in this thread are good ones. I'm just
wondering why you don't make your own antenna. Even buying
commercially made parts, the cost should be much cheaper, and it
really isn't that difficult.

We can, if the noise happens to come from a null of the Beverages
pattern and the signal doesn't.

They might have said that, but that isn't how they perform in the real
world over any kind of soil.

>Poor soil is the key to the comparison with a quarter-wave vertical. It
>helps the Beverage and hurts the quarter-wave vertical. The
>two-wavelength wire has considerable gain in the general direction of
>one end if terminated by a 500 or 600 ohm resistance.

It has no more gain terminated or unterminated. All the termination
does is reduce the backfire sensitivity more than it is reduced
without termination.

> It has
>considerable gain in the direction of both ends if no terminating
>resistance is used. Most of this gain is dissipated by the lossy earth
>that is so close to the antenna, but enough remains to make the Beverage
>competitive with the quarter-wave vertical which has no gain over a
>dipole and over poor soil can itself have considerable loss, but it is
>not so lossy as the Beverage.

I've had Beverages since 1970 or earlier in many dofferent locations.
I've never seen one get within 15-20 dB of a vertical on 160 meters.
No one else I known over the years has seen one equal a vertical
either.

They don't model that way, they don't work that way.

> So, according to the War Department, the
>signal transmission and reception capabilities in the directions most

>quarter-wave vertical. The Beverage`s ground loss just about offsets its
>directional gain so that it is equivalent to a quarter-wave vertical
>over lossy soil.

A Beverage installed over lossy ground is down so far it's very poor as a transmitting antenna, the directive pattern is about what you can get from two verticals phased.

Been there, done that....and so have hundereds of other people. Get a MODERN copy of text showing Beverage performance and you'll not find anyone who agrees with what the War Department imagined was happening.

Uh...this is wrong. But I don't want to embarrass you.

I measured --if you believe MFJ wattmeters--520 watts out. That's CW. There is NO WAY I would run that high a setting on phone, as I can tell you right now it run NON-LINEAR at that power level. Splatter? No thanks.

I never run the amp past 400mA peaks on phone.

Anyway, has ANYONE been able to get 1 KW out from an SB 220 on 10M--with a 120V line?

Broadcast installations on urban roof tops can have compliance problems.

When we did compliance studies on our installation, with the antenna on
a 1040 foot tower in a suburban location, we were easily within compliance.
Even with 632,000 watts ERP up there, RF field strength at ground level
is well within the guidelines. We removed all two way equipment from the
tower (to reduce wind loading when we added the HDTV antenna), so there
are no longer issues with controlled exposures to workers servicing such
equipment. (I lost my repeater site on the tower due to this.)

But our competitors on channels 54 and 69 with antennas mounted on
downtown roof tops have had problems. The first and most obvious problem
is that they had to interlock access to their rooftops. In other words, their
transmitters have to shut down any time anyone goes out onto those
roofs.

This is a problem since the roofs are shared with other communications
services, and with the mechanical equipment for the buildings. So when
building maintenance needs to go out on the roof to grease the pumps
and blowers on the cooling towers (a daily chore), the stations had to
shut down. To get around this problem, the stations had to pay to have
such equipment replaced with water-water heat exchangers that don't
have to be located on the roof. This was very expensive. They still have
to shut down when the two way companies (or hams, we have a repeater
on the same roof top as Ch 54) need to change or repair an antenna or
feedline on the roof top. (In fact *everybody* has to shut down, because
the exposure regulations are for the total net field of all emitters at the

site.)

There were also problems with the mechanical rooms below roof level where elevator equipment and two way communications equipment racks are located. The stations have addressed that by installing shielding to lower the RF levels in these areas. This has not been simple since there are many feedlines coming from antennas on the roof to the equipment racks in the rooms below. Lots of common mode chokes have been required to keep the cables passing through the roof shield from conducting excessive RF down into the equipment rooms.

Of course these are all controlled exposure situations. Problems with uncontrolled exposures to the general public are less, but not totally absent. The inverse square law comes into play. Height and distance are our friends in reducing uncontrolled exposures. But workers in offices in nearby buildings could suffer excessive exposures. Metallic tinting on the windows of those offices took care of that. (The curtain walls have enough metal mesh in them to provide adequate shielding, but the windows were a problem.)

Some AM stations have had issues too. One station, which was originally in a rural location when it was built 75 years ago, is now in the middle of urban sprawl. In fact, it is in the parking lot of a mall. They have had to close off a portion of that parking lot to come into compliance with the uncontrolled exposure limits. (The limits are higher at low frequencies, but the antennas are at ground level, so the inverse square law isn't as helpful as it is for installations with the antenna well up in the air.)

STLs and fixed point to point links generally haven't been a problem. For obvious reasons, they are aligned to avoid having the beam pass through buildings or other points the public might frequent. They are also quite low power, in the 1 to 10 watt range. There are still some controlled exposure issues, IE don't stare into the feedhorns, but typically nothing of real concern.

Our satellite uplink truck is the biggest concern. It runs up to 600 watts into a 2.1 meter dish. It is possible to cook hotdogs held on a wooden skewer in front of the mouth of the feedhorn. But the dish points generally up when in use, and the public can't easily get to a point in the beam. Our truck operators do have to exercise some care to avoid excessive exposures when working around the feedhorn (the beam spreads when it illuminates the dish, so intensity is much less anywhere except right at the feedhorn.)

>Rick K1BQT

Rikki,

You are using a common misconception to estimate feedthrough that is
not accounted for in power input readings.

The current increase caused by driver feedthrough is already added to
the plate input power. A portion of the drive power contribution to RF
output already shows on the current meter.

The voltage contribution by the driver does not show, because the
meter reads HV from the supply instead of the voltage diffeerence
between the anode and cathode.

Adding the RMS cathode voltage on the negative exciter swing at the
cathode to the HV gives the approximate "hidden" contribution by the
exciter. Multiply that quantity by the efficiency to get the output.

You'd be lucky if the driver is contributing 30 watts to the output.

The down drop becomes part of the radiating system. Your antenna will
be like an off-center fed dipole with a "bottom hat". If the distance
from the feedpoint to the end of the radials is about 1/2WL, you should
be in pretty good shape. Why don't you model your antenna? There's a
free demo version of ELNEC available from www.EZNEC.com

Seems you could feed your antenna at ground level in which case it
becomes an inverted-L. If you run your down lead drop close to your
coax, the coax shield might as well not be there.

I kind of agree. I've never been a great fan of random wires. If I were to do what he wants to do, which seems to be running a appx 1/4 wave or longer of "random wire", I think I would just hang a radial for each band from the feedpoint of the antenna and let it just hang or slope down towards the ground, but not touching or connecting to ground. In effect I would be using a vertical dipole. Not the greatest setup, but at least the antenna has a radial to work against. But you will need a resonant radial for each band to be used. Trying to run wires to a counterpoise at ground level will be very unpredictable and the wires will act as part of the antenna. But even with the radials it will be unpredictable for many bands with the single random wire. I don't know if it's possible, but he would be much better off trying to string up a

dipole of any length and feeding with ladder line to the tuner at the
shack. MK

I wonder why someone would run a dual 3-500z amp with insufficient wiring. No real problem running 110v, and the amp should do fairly close to normal assumming you have the thick wiring to handle it. "For the sb-220 seems 30 amps at 110v would be about the right wiring". And I'd have to wonder about the amp if it only did 2300v at idle. Sounds kinda puny for a sb-220. Heck my sb-200 does 2400v at idle. "dual 572b". My dual 3-500z amp a henry 2k classic. It's idles at about 3200-3400v depending on voltage on high tap. The guy I got it from used it on 110v for a while. I got a full KW output on 10m according to his test notes. But usually at that point he would blow his breaker... He had to idle it back to keep the breaker happy for that room. Myself, I run it from 220v. Actually, more inline with 235-245v being we have happy voltage here. My henry will do nearly 1300-1400w with 100w drive on 80/40 etc. And my high voltage will only drop maybe 150-200 volts. Say 3200 down to 3000-3050 or so if I remember right. Much stiffer PS than the heath. The meter bairly moves on normal SSB speech. But, I'm gonna switch to solid state PA before long. Will keep the henry for heavy duty stuff. New amp likely will only be 500-600 watts or so. And I'm gonna build it to save money.Well, enough for this non antenna talk... MK

2192. VLF antenna/receiver grounding

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-16 00:00:00 UTC
From: Cindy Salwen <csalwen@northeast.net>
Message-ID: <33m7ssoufbkuvsa09t81ktk4ebfn64q8j3@4ax.com>
Source record: 180603

Hello,

I have an HP10509A VLF loop antenna sitting on top of a 10m tall steel pipe mast which is set into a concrete base. The coax connector on the antenna has its shield connected to the antenna body which is (I assume) electrically grounded down through the mast. I have a lightning arrestor in a weather-proof metal box mounted to the base of the mast and also grounded to an 2.5m ground rod. So the antenna is also grounded through the coax shield. I have a connection from the ground rod to the water pipe which comes from the street main, which is also where my breaker box is grounded.

I have some questions:

1) Should I somehow interrupt the coax shield that runs from my HP117 VLF receiver to the arrestor box to avoid a ground loop? (The receiver is 'power' grounded through the power cord to the breaker box, and most likely through the electronics rack along with all of the other equipment.)

2) Should I interrupt the center conductor of the coax with a HV capacitor? (I have a 10nF 15kV cap I can use. Would that be OK at 60kHz?)

3) If the answer to 2 is yes then I need to provide the antenna with 35VDC to power its preamp. Should I ground the power supply's case to the breaker box but have the output 'floated' relative to the breaker box and grounded at the mast base?

Any help would be appreciated.

Thanks,

Scott

WSB's AM antenna is not in midtown Atlanta, never has been. It is in DeKalb
county, about 7 miles east of midtown. If this was more than 15 years ago,
you may be thinking of WGST. WGST's antenna was on the Georgia Tech
campus (the Georgia School of Technology station), but it was moved to north
Dekalb county when it was sold to Clear Channel Broadcasting. There are no
AM transmitting sites in midtown at present.

>In some of the local Atlanta skyscrapers, say the BellSouth tower or
>NationsBank tower, etc... the folks sitting at their office desks 8 hours
>per day 5 days per week probably feel that they can almost reach out and
>touch that 50 kW clear channel MW antenna.

The only midtown broadcaster is WTBS, with transmitter and tower located
at 1018 West Peachtree. The tower is 1040 feet AGL, and the ERP is 5 MW
(peak) on channel 17. The roof of the Bell South tower is 618 feet AGL, well
below the main lobe, and is 8 blocks away.

I have a new TV antenna that needs to be converted to 2 meters. So far have drilled out the elements and cut them to length acroding to at least one web site advertised on arrl. what gets me is ive come acrost more then one with different specs. Can somone tell me which is the right way? 16 inch or 20 inch spacing between elements? This is just one example these pages state.

Hi
Thanks

I am sending this message to all who replied on
the MFJ Tuner. Also sending in the order received.

This is embarassing
QLF QLF ON MY PART

The MFJ Tuner Brought 17 emails in 2 hours and I could not figure out
why!
I only got one email for another item ''the 18 Ft. tower.

Then I read what my Clerk posted
Wow $15.00 HELP??!!!
Should be $65.00 and still a bargain.
My Clerk operates on qrp brain power.

So in the order of received e mails I will accept the first re bid for
$65.00
I do not want to make it a contest so no need to bid over.
It is my fault so I will not profit from it.

I apologize for the Trouble and to be fair I am correcting the Post.

Will be back to all re-bidders regardless if they do not get to buy it.

Source record: 180612

Mak:

I am sure that you will find and inverted "L" configuration easier to set up and operate.

Makes a great restricted space all band HF antenna.

Run the inverted L wire up and out for as long as you can manage, then feed it near the "actual" ground [not high up in the air as you propose] against "a few good counterpoises" of approximately 1/4 electrical wl at each of your favorite operating frequencies.

And then "force" feed the antenna against the counterpoises with a good low loss [read high power] tuner. If you find there is some frequency or band on which your tuner will not force feed the antenna, simply cut a couple of feet off the end of the inverted L and start over.

Lay these counterpoises out in the garden/yard and bend them to fit the available space.

Any random length for the aerial "L" shape should work well providing it is at least 1/3 wl at the lowest frequency you desire to use. Try Reg's program to see approximately what the impedances will be on your favorite bands.

If you wish to optimize things, "hand" tune the counterpoises at your favorite frequencies by cutting [shortening] the lengths of the 1/4 wave counterpoises for maximum counterpoise currents at those favorite frequencies.

Fun and easy to build and remarkably effective. Not a contest winning antenna set up but great for general all around hamming.

Over the years I have had great success with these "stealthy" easily hidden unobtrusive simple all band inverted L configurations.

>Doesn't uncorking your station at the LDS PA system at the height of their
>event constitute misuse of one's ham privilege with the potential intent to
>violate a religious sect' s civil rigths??
There is no PA system; I do not interfere with the activities of
neighbors--especially those who are also good friends; My ERP (actually its
EIRP) couldn't possibly be 12,000 watts as I am incapable of producing a
kilowatt of output power;and finally you have profoundly misquoted an earlier
post, Here it is:

<<IF I was running a KW, then my far field ERP would be close to 12,000 watts.

Now: IF you were louder "anywhere" than me, BY 20 dB, then your ERP would be
1,200,000 watts.

That's 1,200,000 watts.!!!

Chuck--have you checked the minimum compliance distance on 10M for 1,200,000
ERP?

It sure sounds like a visit by the FCC would help you check your numbers
properly, or reduce your ERP to acceptable levels.

73
Chip N1IR>>

You've already calculated and
>published your ERP at 12,000 Watts (correctly or not), indicating a full
>understanding of your station's potential to commit harm through powerfully
>directed RFI.

No. That is not correct. I did not do so and I did not say that. However, IF I
was running a KW output, then the EIRP would definitely approach 12,000 watts
on the 10M FQY. For the gain, in dBi, above typical ground for my location (and
a cncise and clear comparison to a dipole) see :

http://www.fractenna.com/ham/hampage1.html

> Civil rights violations implemented by a member of another
>faith
>(intentional or not) would surely take precident

Do you mean 'president' or 'precedent'?

over FCC rules in any
>lawsuit
>or licensure hearing. Better check with your lawyer before you go for #311!
>
>I'm not kidding. If I were there, I wouldn't touch that microphone on a bet!

>

Why don't you present your case to the FCC? They are always welcome here.

I don't know nor care to understand your perverted view of the LDS Open House, but it is a wonderful event, with no 'PA'. No one is put out by it, and I, for one, thoroughly enjoyed it. Then again, sharing the happiness of my friends is always enjoyable.

Why don't you take the tour yourself? Their web site is:

http://www.bostontemple.org

If, after you tour, you end up being inspired to be contrite for some reason, you may also drop by and visit if I am around.

I don't know what dates are still open, but there is nothing special about Sept 16.

The dedication is Oct 1.

Source record: 180641

Steve,
First, forget about hinging a tower 100-120' tall, that just
won't be very practical.
If your not very familiar with erecting towers the best advice
for you is to talk to people who are, or a commercial out fit that
erects towers. There are a number of things that come into play when
dealing with towers that tall. Follow the recomendations of the
tower manufacturors, and you might over do those recomendations by
a bit (remember they are ~minimum~ safe standards).
I know this isn't very helpful about specifics, but there are
quite a number of things that depend on your location/conditions/etc.
'Doc

2217. AM aerial

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-16 00:00:00 UTC
From: "Paul.A.Bowden" <Paul.A.Bowden@btinternet.com>
Message-ID: <8pvh9j$58s$1@uranium.btinternet.com>
Source record: 180643

I know nothing about radio, but hope that one of you may be able to help with what will probably be a rather stupid question - please forgive it, if it is!

As part of a hi-fi system I have a NAD 4225 radio tuner, which I use for FM listening with an external aerial. However, I listen a lot to AM broadcasts (especially French LW stations around 1800 and 1300 metres), but can't do so on this tuner, there being no internal aerial. There is plenty of space outside for an external wire aerial, but I haven't the slightest idea of how to go about this or whether it would be of any use (I'm afraid it needs to be something cheap and do-able by a DIY moron)

I would be really grateful for any help - and apologies for lowering the tone and technical level of your group!

Thanks

Paul Bowden
(Lincolnshire, UK)

There was a review of it and other space efficient antennas in the May
1998 QST. It compared the ZR-3, Hexbeam, ISOTRON and the
Alpha-Delta/Outbacker thing to an R7000.

2221. W8NX Trap Dipoles

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-16 00:00:00 UTC
From: Michael Hart <mhart@NOSPAM.terrigal.net.au>
Message-ID: <39c3605a@turakina.six.asn.au>
Source record: 180647

I am interested in making a trap dipole as described by W8NX in August 1994 QST. I need to build the 80, 40, 20, 15 & 10 metre version.

My trouble is that in Australia the section of the 80 metre band that is predominately used is between 3.5 and 3.7MHz (centreing around 3.6MHz). The antenna described has an unsatisfactory SWR at these frequencies and is tuned more to 3.8MHz.

I do not know which section of the antenna to lengthen to lower the resonant freq on this band without affecting the other bands. If someone could let me know what to do I would appreciate it.

Lengthen the wire on the end of the dipole - just beyond the 40 meter traps.

Am busy putting out food; don't understand yourt question.

In the far field, with reasonable ground models, 10.8 dBi for a 2 element yagi
is very reasonable as an assumption.

What's with this 1 KW stuff? The best I can get IN on my SB220 on 10M is 1/2
amp at 1700 volts. How is that a KW OUT??

:
:73
:Chip N1IR

1700volts @ 1/2 Amp is still 850 watts (I can do basic math.) Then
assume the amp is 50% (ballpark figure here) efficient. 425 Watts,
there. Then the db loss from the Frick&Fracktenna, and you might be
radiating about a watt and a half. ::snicker::

Just my two cents, your mileage may vary.

I'm retired now, but still have a lot of
contacts on police depts all over the US.
The police are very familiar with Chip
in his jurisdiction but when I talked
with my old academy chum day before
yesterday, he said there are no
alerts regarding the open house re
parking or any other problems. There
are no special plans to tow anyone that
parks legally on a public street.

I'm in town this weekend. Haven't seen anything
special happening this am so I went back to work.

They've heard of you, Chip, but just
not this time.

Retired Sgt Lumpy

From: Mak <Asylum140@NOSPAMbtinternet.com>
Message-ID: <8pvubpnir1@neptunium.btinternet.com>
Source record: 180656

Gentlemen, your estimates please on the impedance of my proposed HF aerial:-

Resonant long wire (hopefully), earthed from the feed point near the top of my house.

I ask because I need to feed it with coax and guess I will need a balun up there to help match it. Any ATU has to be at the other end of the coax (tx) and (obviously) I don't want the coax radiating.

73s.

2232. Re: W8NX Trap Dipoles

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-16 00:00:00 UTC
From: Terry Redding <terry@oltraining.com>
Message-ID: <39C37F96.8C3D6A@oltraining.com>
Source record: 180658

If you assume the electrical length of the 80 meter dipole is 468/f MHz or 468/3.8 MHz or about 123.16 feet. And if you compute the target electric length as 468/3.6 MHz or about 130.00 feet. You can then compare the two computed lengths (130.00 - 123.16 = 6.84 feet) and conclude that the overall length of the antenna must increase by about 6.84 feet in order to lower the 80 meter operating frequency from 3.8 to 3.6 MHz.

I am not sure how the capacitive hats effect the antenna other then to generally assume they allow the antenna to be shorter and possibly a bit more broad banded. So I would start by dividing the 6.84 in half and then adding the resulting 3.42 feet to both sides of the dipole, just past the 40 meter traps, and then see where the SWR plots.

What does "earthed" mean? Unless you supply a counterpoise at the
feedpoint, much of your RF current will flow back down the outside
of your coax.

Sigh!

Thought I'd show some of the OM's this NG waiting for 10 to open:-)(

Terry,

I get 2300 volts idle and 1700 volts on with 120volts line. If you have 240v set I bet you can get better than that.

Wayne Grauel wrote:
"Does this (Beverage antenna) work for transmission too---?"

The War Department`s think tank (MIT Radiation Lab) had this to say about the Beverage in 1945:
"The Beverage antenna (often) consists of a single wire, two or more wavelengths long, supported on poles at a height of 12 to 20 feet above ground.
This antenna is directional and is used primarily for either transmitting or receiving VERTICALLY polarized ground waves.
With two wavelengths of wire, an efficiency equalling that of a quarter-wave vertical can be expected in the h-f band over poor or medium soil."

Poor soil is the key to the comparison with a quarter-wave vertical. It helps the Beverage and hurts the quarter-wave vertical. The two-wavelength wire has considerable gain in the general direction of one end if terminated by a 500 or 600 ohm resistance. It has considerable gain in the direction of both ends if no terminating resistance is used. Most of this gain is dissipated by the lossy earth that is so close to the antenna, but enough remains to make the Beverage competitive with the quarter-wave vertical which has no gain over a dipole and over poor soil can itself have considerable loss, but it is not so lossy as the Beverage. So, according to the War Department, the signal transmission and reception capabilities in the directions most favored by the Beverage are the same as for the non-directional quarter-wave vertical. The Beverage`s ground loss just about offsets its directional gain so that it is equivalent to a quarter-wave vertical over lossy soil.

Best regards, Richard Harrison, KB5WZI

Hamsticks do an OK job on the higher bands but on 75m, you can't
tell the difference between a Hamstick and a 12ft whip driven
by an SGC-230 autotuner. Ever feel of a 75m Hamstick at the top
of the coil after transmitting with 100 watts? It's almost as
hot as a 100 watt bulb.

I have posted the summary of rankings for 75m mobile antennas on
my web page based on the results of three 75m mobile shootouts.

Hi Terry--

What kind of power can you get out? I used to collect and sell SB220's and the best I could get, on a 240 line, was 1150 out on 40M.

On this one, which is on 120v, I can get 850 w IN, tops, on 10M.

At this time, there are only a handful of researchers making that claim; the majority of their peers do not accept their results as conclusive. Of the few studies I have perused, the scientific flaws are pretty evident, once they are pointed out.

I think that the media, not science, is responsible for most of the hype.

For a very balanced view on the subject, see:

http://www.seas.upenn.edu:8080/~kfoster/comar.htm

and

http://www.mcw.edu/gcrc/cop/cell-phone-health-FAQ/toc.html

The latter is quite comprehensive and well received in the scientific community, as a whole.

Message-ID: <4eAw5.252$tn.7677@typhoon.ne.mediaone.net>
Source record: 180623

Over the years in numerous field day set ups, a 200 - 400 ft wire
placed on the ground and used as a receiving antenna enabled many
contacts with early summer QRN that would have been otherwise impossible,
using the transmit antenna! Run the wire SW x NE, (here in the NE) making
sure you don't blow the front end of the receiver when you transmit, you
will be amazed.

Also, to get 5 - 10 dB additional signal into the receiver, use a 16:1
transformer
from the wire to the receiver input. This requires a reasonably good ground
at
the end of the wire. I've found that a single 8' ground rod is usually
sufficient.
This is for 160 to 40 meters. The 40 M performance isn't too impressive,
but most of the time
there is an advantage. This is over average soil. In one case on the
seacoast I tried this
setup and it still worked, but my feeling was that inland, the improvement
over the transmit
antenna, a dipole at 40 to 70 feet up, was greater. Resistive termination
to get F/B
does help but in field day set ups it's another complication.

On a several occasions I had a remote relay switching in a termination and
most of the time
it didn't help much. The null off the back is sharp. The Beverage Antenna
Handbook
by Victor Misek, W1WCR, contains a description of the steering wave array
which
does work very well. Check it out. It provides a steerable rear null and
does work.

BTW, a seacoast location (within 100 feet of the ocean) is always better
for any antenna!....with the possible exception of a good inland hill,
providing
200- 300 ft above average terrain elevation for 10+ wavelengths.

Message-ID: <ank5sssc8vq5mdtbu0n8v913k1pkq5bt1h@4ax.com>
Source record: 180625

Bill,
I built a 4 element yagi using the specs from the DL Style 7 element
yagi that has been in the ARRL Antenna Book and the Handbook
for years. Just using the first four elements from that works well,
and is small enough it can be turned with a U100 rotor.
Spacing
Ref 18' 1/2"
Driv 16" 10 1/2" 5' 10 1/2" from Ref
1Dir 16' 4' 10" from Driv
2Dir 15 10 1/2" 5' 6" from 1Dir

Driven element uses a gamma match on the one I built and the
SWR curve covers from 28.025 at 1.6:1 to 28.700 at 1.7:1.
I used 1 3/8 for the boom, the two outer elements are mounted
on the top of the boom, and the two middle elements are mounted
on the bottom of the boom, this kept the elements in line with
what little boom sag there was.
good luck and have fun
Dave

Doesn't uncorking your station at the LDS PA system at the height of their event constitute misuse of one's ham privilege with the potential intent to violate a religious sect' s civil rigths?? You've already calculated and published your ERP at 12,000 Watts (correctly or not), indicating a full understanding of your station's potential to commit harm through powerfully directed RFI. Civil rights violations implemented by a member of another faith (intentional or not) would surely take precident over FCC rules in any lawsuit or licensure hearing. Better check with your lawyer before you go for #311! I'm not kidding. If I were there, I wouldn't touch that microphone on a bet!

Message-ID: <8pukdiogf1@plutonium.btinternet.com>
Source record: 180627

Roy, I can only repeat - use your own program Eznec or any later variant. Model any weird shape and size of loop you fancy.

Should you find a shape of loop having the same or smaller perimeter than a standard 1/2-wave resonant circle but with a radiating efficiency greater than the circle please let us know.

Constraints : - identical diameter copper conductors of the loop and the standard circle. The perimeter must not be greater than 1/2-wavelength. The standard circle is not a continuous loop but has a sawcut in it such that it is half-wave resonant as with a magloop without a tuning capacitor. The antenna must be remote from ground.

The loop may be tuned by inserting a (lossless) capacitor in series as with a magloop.

No restrictions in the manner in which the loop is fed but feeding arrangements need not be included in the model.

The foregoing is of course hypothetical. Because I predict an inexperienced person searching for the holy grail would give up after 4 or 5 attempts and getting nowhere. As for you Roy, you will probably never start a task which you recognise as being an obvious waste of time before you click on the start button.

It is obvious because, for example a 5-feet diameter standard circular loop, with a 2" diameter conductor, 1/2-wave resonant at 30 MHz, has a radiating efficiency of approximately 99.85 percent. Beat THAT with any other shape of conductor ! With what other shape would you start ? A square ? A fractal ?

<wgvideo@attglobal.net> wrote:

>OK Tom (and group), I'm learning a lot here, ...
>
>1. What is a beverage antenna?

It was named after a fellow who worked for RCA named Beverage.
It's a simple long low longwire, usually terminated in a resistor to
make it uni-directional towards the resistor.

It has about 450-600 ohm impedance, usually. The impedance varies with
height and soil conditions, as well as wire size.

>2. In lay terms, why does it work so well to the ground

It doesn't work "well" so far as gain goes. It is a rather lossy
antenna, usually around 20 dB weaker than a full size antenna. For
receiving that isn't important, because any lack of gain can be made
up in a amplifier ahead of the receiver.

It works because the earth below the antenna is lossy, and that loss
causes a potential difference along the earth. One way to view it is
the wave "tilts" because of ground loss, so the wire "sees" that
tilted wave.

With lossless ground below the antenna, a Beverage will almost go
dead!

The long length makes it directional, and that reduces unwanted
noises.

It is a very ineffective way to get directivity, but that is offset by
the ease of construction. It is a very "forgiving" antenna, even if
you don't install it perfectly it's hard to mess it up.

>3. What effect does his resistor in the end have (if any)

It makes it more uni-directional. Even without the resistor, the
Beverage is somewhat unidirectional firing away from the feedpoint.

The resistor terminates the antenna, and reduces standing waves in the
wire. That's what makes it unidirectional. Ground losses below the
antenna make it somewhat unidirectional even without termination,
especially if the antenna is long interms of wavelength.

Once it's about two wavelengths long, you are about at the limit of
performance increase with length.

>4. Does this work for transmission too or better for just reception?

It's a poor transmitting antenna, because of earth losses.

From: Terry Redding <terry@oltraining.com>
Message-ID: <39C2F888.8A4E9566@oltraining.com>
Source record: 180633

If I was going to pick an approach to antenna design - it would have to be the arrow / target method described earlier. Very early in my amateur experience I spent a very enjoyable month, as a novice, experimenting with a vertical antenna. I was on vacation in the Finger Lakes region of New York state and had plenty of time to just "see what works." I thought the target vertical mounting point was on the front or rear of a travel trailer - but I was wrong.

I started the process by hanging a parallel dipole for 40 and 80 meters between to tall pine trees. The ends of the dipole were at about 40 feet, the apex drooped down to about 25 feet. That became my reference antenna. I also had a bread board antenna tuner that followed a design from the Handbook. Thus I could build antennas with a 1:1 match design goal, but could actually load just about anything.

Next I had an 18 foot tall vertical that was base loaded. It was a very simple vertical sold by High Gain at the time. The base loaded coil was adjusted by moving a shorting clamp from the bottom of the coil to the the top adjusting the operating frequency from 10 meters through 80 meters.

Once the dipole was setup so that it enjoyed the lowest SWR in the novice band of 80/40/15 meters I turned my attention to the vertical. My goal was to create the optimum mobile operation situation for a travel trailer. In most cases I knew that I could put up a dipole as an inverted vee. But I was hoping to achieve superior results with the vertical.

First I tried bolting it to the bumper and the tongue of the trailer. Neither location worked well. The dipole easily outperformed the vertical in all receive and transmit test. Generally the dipole out performed the vertical by several S units. Routine contacts were made with the dipole, but they were difficult with the vertical. It was such a poor performer. I was only able to load the vertical by using the antenna tuner. In all cases the vertical put a lot of RF back inside the travel trailer and the key - felt hot - to the touch when transmitting.

Then I had the bright idea of mounting the vertical to a cold water pipe that stuck up on the middle of a large grass field. Still very poor performance, though at least I was able to tune it for each band and load it with out using the antenna tuner. I then added a grounding rod to the cold water pipe - but no improvement was noted.

During the week of experimenting I counted myself luck to have an understanding wife and set of in-laws. The antenna project consumed all of my time.

In the second week of experimenting I bought a ten foot mast and tried mounting the vertical elevated at the front, back, and along either side of the trailer - things were looking up. The antenna was performing better - but the dipole

was consistently better in all cases.

It was during this phase of experimenting that bought wire and tried a counter poise for the first time. Hey - what do you want from a young Novice. The elevated vertical with counter poise was tunable and load able without the antenna tuner. But the dipole was still better. I was getting ready to accept the poor performance of the vertical as being as "good" as it gets. But I was troubled by the mounting mast having to be taken down and stored each time i moved the trailer.

I decided that what I needed was a water pipe flange bolted to the top of the trailer as a mounting point. But that would not be very strong. The trailer had a thing metal roof with about 16 inches between rafters. I settled on having a metal mounting plat fabricated and mounted permanently to the top of the trailer in the middle of the roof with the flange permanently bolted to the plate. That way I could have a 24 inch pipe screwed in to the flange and the vertical claimed to the pipe for a very rigid mounting system.

A visit to a local machine shop and a day later I had a nice plate ready to be bolted to the top of the roof of the trailer. One day after that I had it bolted to the top with the flange and vertical mounting pipe. That day I put the vertical up, started the tuning process and was very pleased and surprised to note that the vertical could be tuned to a 1:1 match on any ham frequency, on any band I cared to try.

More surprising was the signal reports. The vertical was receiving considerably better then the dipole. Actually - it was unbelievably better then the dipole. During my schedule with WA6INF at Fort Sill, who normally I could work in the evening with difficulty, was now giving me a 599 report. The vertical was now several S units better than the dipole. In fact - in some cases - vertical to vertical - the vertical was able to achieve an S9 + 10 to 20 db on receive, while the vertical was barely able to detect the presence of the signal.

The target ended up being a mounting point in the middle of the trailers metal roof with a low resistance ground path. A great summer vacation. Great radio fun, and I had many years of the vertical on the trailer roof being the best antenna I owned.

Thanks Terry,

There are THREE wires beyond the 40m trap. They are a 4.9foot section then a 6foot branch (capactive load it is called) then a 16.1foot section. My initial guess was to lengthen the 16.1' section [by how much I don't know] but it seems you are suggesting to lengthen the 4.9' section. I would have thought this would also affect the other HF bands then.... Can you confirm this is the right section to lengthen please.

rgds.

Michael

Not at all;

One of my main areas of research is SETI. I have done SETI for over a generation and published extensively in it. In the last few years I have published and presented several fundamental papers which now, and for generations, will be among the guidelines for how SETI should be done and how it can succeed.

A KEY aspect of this is EIRP. Thus if I am incapable or incompetent in this regard, I, and many others, need to know NOW before any damage is done.

So, no troll: show me how my estimate of EIRP from N1IR on 10M with my Sb220 and 10M FQY is flawed.

Your humble servant,

Chip N1IR

Well...

I don't know how dry they were...

But I have personally run 100 - 200 watts into ladder line fed dipoles just laying over the tops of trees with no insulation. I literally just threw the antennas up and over the tree tops.

I did this on field day operations on several occasions and on other "operations" often just for a few days of hamming at a temporary or transient location and while the weather was warm and dry with no ill effects that I could observe on either the transmitter, antenna or the trees.

I wouldn't consider it for a "permanent" installation and I'd be careful that humans and animals didn't come in contact with the bare wires, but it worked for me, and probably will again.

generally a loop with its top at the same height as an inverted v will perform worse than the inverted v(though only by a little bit). this combined with having double the wire in the air and the associated problems with ground and other obstruction clearance generally makes it better to run a plain inverted v over a loop. after modeling several loops and v's for installation here it is fairly obvious that this is because almost half the loop's radiation comes from the very bottom, closest to the ground and anything else that is in the way.

Roy:

Apparently only Ph.D.'s and such are impressed by DXCC.

Any certificate will impress a Ph.D.... they are certificate obsessed.

Now some just perfect antennas and design equipment and don't need a fancy certifiicate to prove they can talk fast.

Ph.D., bah... obsessive test takers and certificate hunters, not confident in their own abilities they seek afirmation in sheets of parchment with fancy lacework on the borders.

Thoughts, comments?

Oh well, garbage in, garbage out.

I speak from experience using a Beverage antenna for years in Lisbon, Portugal to listen to W.R. Murrow give the evening news broadcast from WCBS, 50 KW non-directional on 880 KHz in NYC. It was dependable but subject to some fades which were conveniently solved by rocking the tuning down to 870 KHz to pick up WWL in New Orleans, Louisiana which simulcast the Murrow broadcasts with WCBS. WWL uses an East-West directional array with 50 KW and though 2100 miles from Lisbon vs. the 1600 miles between Lisbon and New York, the signal strengths were normally about the same.

I used the FCC formulas to see what signals I should expect in Lisbon. It turns out that this is an intensity of about 0.85 mv/m at 1600 miles. John Cunningham shows how to do this in "The Complete Broadcast Antenna Handbook."

Were the Beverage as bad as Tom makes out, it would not have produced the satisfactory results I enjoyed.

If Tom`s Beverage antennas don`t perform so well, maybe they are not 12 to 20 feet above ground. Maybe his ground conductivity is too high for the necessary wave tilt. Maybe Tom`s Beverages aren`t 2 wavelengths long. I don`t know what Tom and his acquaintances are doing wrong, but if you don`t need top performance it doesn`t make any difference.

Best regards, Richard Harrison, KB5WZI

Terry:

You've got a Ph.D. and never heard of a fractal antenna?

Disgusting! Chip will soon fix that!

Terry... get with Dr. Cohen for a few emails and he'll bring you up to speed, even perhaps certify you with a fractal certificate.

In case you don't know the certificate looks great framed beside your Ph.D. diploma. It's a modified certificate that's made from a DXCC certificate embossed with a seal from the Fractal Antennas corporate seal. Of course you will have to send Chip a notarized statement that you worked DXCC in no less than 30 minutes to get one of these awards.

Enjoy...

I agree Richard. The War Department is famous for that!

>I speak from experience using a Beverage antenna for years in Lisbon,

I've used Beverages since around 1970, and have spent thousands of hours listenting to them. I have over 30 Beverages right now.

I also associate with dozens of people who use Beverages, and there have been may articles written.

All agree, the Beverage is nowhere near as sensitive on receiving as a 1/4 wl vertical over any kind of soil.

>Were the Beverage as bad as Tom makes out, it would not have produced
>the satisfactory results I enjoyed.

Nonsense.

Everyone who uses a Beverage understands they have negative gain.

Negative gain has nothing to do with S/N ratio on receiving, because the noise floor on HF is established by external noise propagated to the antenna. Even if a receive system has -20 dBi gain below 15 or 20 MHz, it will limit on external noise.

Once that happens, gain becomes unimportant. Directivity is the only thing that matters.

Toi make my Beverages have the same signal level as my transmitting antennas, I have to amplify the Beverages ~10 dB and pad my transmitting antennas about the same amount.

If Beverages had anywhere near the FS of a 1/4 wl vertical, people would be using them for transmitting. The radiation resistance of a Beverage is under one ohm, the loss resistances are over 400 ohms.

>If Tom`s Beverage antennas don`t perform so well, maybe they are not 12
>to 20 feet above ground. Maybe his ground conductivity is too high for

>if you don`t need top performance it doesn`t make any difference.

My acquaintances number well in the 100's that are "doing something wrong" and span a time frame of 30 years. First, that height is too

high for 160 meters and up. At that height the Beverage would start to take on the properties of a low longwire, and radiation from the vertical drops on the ends would become a problem. Directivity would suffer.

Ten feet is about the limit on 160 meters, and progressively less hight as frequency is increased.

I suggest you get a few modern texts on Beverages, build some, or model them on a modeling program. Read ON4UN's Low Band DXing book, or any number of other texts. Relying on one source, especially a Military publication from many years ago (and especially when dozens of other sources conflict with that data), can get you in trouble.

The SB-220 will run as much on 120 volts as on 240 with modern up to code house wiring.

That amp runs 2kW or so peak input. It's quite possible to get over 1000 watts PEP output on ten meters.

Of course someone could have assembled the kit improperly, maybe bending the tank wires around in zig zags or using long leads on the grids or in the input circuits. Did you put in a fractal tank coil?

With 400 mA on the meter during voice peaks you should easily be in the kilowatt PEP output range with normal voice SSB transmissions.

STILL looking for honest answers on how much others get out of the Sb220 on 10M...

I check with NZ1W, and back when we used a couple of SB220's at his QTH (one as backup) we could get about 600w out on 120V and 730w out on 240V.--this on 10M That was after tweaking the coils; putting in 3500Z's etc.

Anyone else ha\ve some actual numbers?

Thanks!

[...]
>> www.c2i2.com/~lasono/dovetron/main.shtml

They have a very odd definition of "isotropic", because they also say:

HALF OF THE RF RADIATES BELOW 45 DEGREES AND PRODUCES BOTH
THE LOW-ANGLE, LONG- HAUL "DX" SKYWAVE VIA F2 AND THE
SHORTER-HAUL E-LAYER "SHORT-SKIP".

THE OTHER HALF RADIATES ABOVE 45 DEGREES AND IS THE
NEAR-VERTICAL-INCIDENCE SKYWAVE (NVIS). IT PRODUCES COVERAGE OF
THE CLOSE-IN 250 MILE RADIUS AREA. UNLIKE LINE-OF-SIGHT SIGNALS
(MF/HF/VHF GROUNDWAVE), THE NVIS WILL REFLECT DOWN INTO VALLEYS
AND CANYONS, BETWEEN BUILDINGS AND BEYOND THE HORIZONS.

70% of the area of a hemisphere is below 45 degrees, while 30% is
above 45 degrees. If the pattern has equal power radiated above
and below 45 degrees then the average power density above 45 degrees
is 3.8 dB higher than it is below 45 degrees. This doesn't sound
very isotropic.

Dennis Ferguson

2282. Rectification in Alarm System speakers from Beam Antenna--help

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-17 00:00:00 UTC
From: jeffreys@cyburban.com
Message-ID: <39c553ed$0$1343$45beb828@newscene.com>
Source record: 180491

My friend, K2ACB installed a Hexbeam antenna on his roof (4.5 foot tripod mounted). With his vertical in the back-yard (about 30 feet from the house) everything is ok.

With the Hexbeam on (its about 10 feet from the second floor), he gets really bad rectification of his signal in the alarm system speakers.

I installed a whole mess of RF chokes on all of the leads coming into the alarm system computer in his basement. I did the same thing at the first floor speaker, but the rectification is still there and quite loud.

All wire is unfortunately unshielded and there is quiet a bit of it to each sensor (one is a montion sensor less than 10 feet from the Hexbeam).

Our temporary solution was to discount the speakers (all they do is announce "You have entered a secure area" (annoying) and the equally annoying whoop-whoop alarm sound (doesn't one just need to have the police notified?).

But, does anyone have any more suggestions?

> through a 4:1 balun. It soes seem to have SWR problems on 15m.

Technically, that's not a Windom. It's simply an off-center fed dipole.
Off-center fed dipoles have vertically polarized radiation from the feedline
and horizontal radiation lobes that is strongest off the long end of
the antenna. Depending upon what is desired, that radiation pattern may or
may not be better than a simple dipole.

> Since the guy on the www page I looked at has actually built one fed by coax
> and measured the SWR on each band I am happy to take his [measured] results
> as fact. The thrust of my question was along the line of radiation
> efficiency.

The feedline on an off-center fed dipole radiates because the currents
are not balanced. Otherwise, it is a wire and is approximately as efficient
as center-fed wires of the same length. Don't put too much faith in the
SWR figures. Loss in the coax lowers the SWR.

The All-HF-Band antenna on my web page is less expensive and more efficient
than an off-center coax fed dipole.

William:

Well no I don't think the Ivy League admissions clerk would accept BU into that distinctive category....

As far as I can determine from Dr. Cohen's postings and from some independent research [I once checked out the title and abstract of Dr. Cohen's Cornell disertation at University Microfilms in Ann Arbor.] I believe Dr. Cohen to be a graduate of Cornell and not of BU. I assume that, although closer to the pine tree line than the ivy carperted forests further South, Cornell is an acceptable representative of the club of Ivy League schools.

Dr. Cohen does claim, in some postings to this NG, to teach at BU. This claim in and of itself is certainly not a comment on the value of BU or of its' programs.

I don't know in what capacity Dr. Cohen teaches at BU... perhaps, Teaching Assistant, Lecturer, Assistant Prof, Associate Prof, Prof, Adjunct Prof, Emeritus Prof, Dean, President, etc... could be any of those... who knows, who cares...

Dr. Cohen is apparently not a terribly effective teacher as evidenced by the reactions of the "students" on this NG and since I have never observed "golden apples" being handed out here by his students or former students I have serious personal doubts as to his suitability to teaching. Perhaps he receives kudos for his teaching abilities in another forum, certainly not here!

In my experience, here on the NG, I have never noted Cornell to officially make a posting on this or any other topic discussed on this NG.

And so, although he takes great pains to inform all and sundry hereon of the fact that he is a Ph.D. graduate of Cornell,... Dr. Cohen's posting behavior here is apparently neither condoned nor approved by Cornell.

All of our institutions of higher learning are under considerable pressure to perform these days and so I would not be so presumptious as to tell them who to hire as teachers.

Peter [Not an Ivy League graduate] K1PO

For what it's worth, I worked in the fire service for over 20
years.
In that time I never saw a tree fire caused by RF. Being interested
in the subject, I've checked national reports for over a 10 year
period,
no tree fires due to RF. I've also used antennas running through
trees
for a number of years, power varying from 100 to over 2000 watts. No
tree fires yet.
There's always the possibility, but I just don't think I'd worry
about it too much. Probably more likely to be hit with a meteorite!

I would advise against the sled kite unless you are flying from a beach or other area that has very steady wind. It is rather sensitive to turbulence and will collapse and crash under less than ideal conditions. The most steady and reliable kite that I have flown (and I have flown most designs), is the delta or delta conyne. I have used both of these designs to lift cameras, banners, lights and antennas. The only real disadvantage is that large ones suitable for lifting are hard to come by ready made. If you are any good at constructing your own though, you can't go wrong with these designs.

I'm looking for a new house and a few I'm looking at have high power lines not far away. I'm wondering what affects on the various HF or even VHF bands the power lines might have. No these are are not so close that my antenna could ever touch. These are maybe 1/4 to 1/2 mile away... any advice is welcome. Can much of the affect be removed with the right antenna type & polarization?

Thanks

>worse than any properly designed antenna.
>

This is probably now a subject for the history of science. Certainly I will support the efforts of any scholar who pursues it.

It probably is the first major technology breakthrough in which the internet--specifically USENET--has been used as a propaganda tool to ATTEMPT to destroy it.

Some quick comments:

1) random structures are fractal. See Valdivia's thesis--available on the web--on random lightning as a fractal antenna;
2) In the case of a small self- resonant loop--such as MI2--the field strength and radiation resistance is incredibly sensitive to the geometry. It has nothing to do with 'origin symmetry' and ''length of the wire'.

I have no doubt that a small handful of other fractal antennas--including random fractal designs--have the capability of similar FOM's. Like to see one that works better though. Haven't seen any evidence for one yet!

99.999% of 'arbitrarily chosen' random fractal designs cannot acheive resonance nor the field strength of MI2 in it's form factor. Therefore it is an egregious lie to infer that arbitrariness is being used.

The orthogonality and the way L and C are produced in a bent wire strongly suggest that MI2 is an optimized struvture in a global sense. The $1000 Fractal Challenge is just such an effort to show a counter/ better example.

So, where is it?

Hey Rick--

With my 520 watts, and the info available on the web on my antenna, what IS my EIRP? Assume, say, a 1 dB insertion loss for the coax. Nice roundoff.

You seem to have severe doubts about my ability to calculate my EIRP, or some other excuse.

And yet you made a serious gaffe in determining the OUTPUT power of an SB220.

I would be curious to know what your CALCULATION of my EIRP on 10M is....

Please show us explictly;

There are several designs for multiband HF antennas eg.

Windom antenna (1939) http://www.shirakami.or.jp/~tada/JA7KPI/windom.html

G5RV (needs a tuner and coax acts as part of the antenna on some bands)

Multiband trap eg W8NX trap dipoles (requires traps and has trap losses)

Can anyone tell me, apart from being not usable on 15m, what is wrong with
the Windom antenna and why it is not used much any more????

Chip:

I guess you will have to read about it in the IEEE publications when I write
the article describing the performance of the arbitrary design re: the
Fractal one.

To state that I am clearly wrong or misunderstand basic antenna concepts
without looking at the NEC results or files is unbelievable. I guess its a
safe way of convincing yourself that you can't be wrong. The more you make
statements like this, the more your true character comes through. What a
bunch of sour grapes.

> Using words like 'directivity' and 'impedance' are cop outs that
deliberately

> avoid issues such as field strength and efficiency. I have no idea why
someone
> who claims to do antenna work would use NEC4 to get directivity rather
than
> field strength, or quote an impedance rather than a radiation resistance
(at

>

Now it's a problem with using nec4. I thought Roy told us that the version of EZNEC Chip uses has a NEC4 engine. Roy also ran my NEC4 file in EZNEC and confirmed my NEC4 impedance data.

>
> Field strength is the salient observable.

a 20
> turn spiral that had better 'directivity' than MI2. Of course it has a far
> lower field strength because it uses 4 to 5 times the amount of wire!

Wrong. Another misrepresentation of my statements by Chip. Here is the full quote of what I said - posted 9/7/00:

"The helical loop has a helical diameter of about 5 inches with about 20 helical turns per side. Using NEC4 to model the structure, it predicts the resonant frequency to be about 13.56 MHz. This is a lower resonant frequency than the MI2 Fractal Loop (I can change the configuration to match your resonant frequency but thought this to be unnecessary). The predicted resistance at resonance is 33.6 ohms which is closer to 50 ohms than the stated 26 - 30 ohms of the MI2 Fractal Loop. I won't state the antenna bandwidth because I do not know how you define it. Using my crude method of determining radiation efficiency, I predict it to be somewhere around 98% with number 10 wire. The predicted directivity and radiation patterns look very good."

Note that I said the directivity looks very good. I never said it was better than the MI2 loop because Chip would not tell me what dirctivity he calculated. Also note that Chip still claims that my loop design (not the design presented in this thread) has 4 to 5 times the wire if the MI2 Loop. I told him it had virtually the same wire length as the MI2 loop. These statements made above by Chip are an outright lie.

>
> Gee! Tiny phased arrays have OODLES of directivity and boy do they stink!

You really should avoid unqualified generalizations. SOME random
structures are fractal. Using your SWAG (super wild-ass guess) technique
(see below), 99.999% of random structures are NOT fractal.

> 2) In the case of a small self- resonant loop--such as MI2--the field
strength

Incredibly sensitive to the geometry? Do you really want to say that?
That statement makes me want to stay as far away as possible from the
MI2. To me, that means if there's an error in a length of a conductor or
an angle between two conductors, then I can't count on the radiation
resistance being anywhere close to what I want.

>
> 99.999% of 'arbitrarily chosen' random fractal designs cannot acheive

Because of its single wire vertical feed, it has most of the
disadvantages of a vertical, e.g. requires a ground plane/
counterpoise. Because of its long horizontal span it has most
of the disadvantages of a horizontal, e.g. requires two supports.

Here's what my 1957 ARRL Handbook says about the Windom:
"The antenna will operate satisfactorily on the even-harmonic frequencies, and thus a single antenna can be made to serve on the 80-, 40-, 20-, and 10-meter bands." It can be inferred that the author thought the feedpoint impedance caused a matching problem on 15m.

Thanks to all so far (and please keep going - I'm checking out all the references/programs as we go) - but ...

I really am stuck for both height and space. This is a softly, softly antenna (idea), simple (phyically) and unobtrusive (I think I can talk my way out of one (or two) strings of wire but that's about all.)

My shack is at the 'wrong' end of the house and the cable run is full of noisey cables - hence my desire to fed with coax. The feed oulet is the highest point in this equation, the aerial must go down in height away from the house. I can't see me making an inverted L fit here - at a push I could run the vertical up first but it would be next to the house brickwork (I had previously discounted this as a bad move - maybe not; what you you think).

A good all-rounder is fine and would suit me to a tee.

The fact is there is not much difference in running coax with its
braid floating and running a single wire. Much of your RF current
will be flowing on the outside of the braid causing all the problems
that you are trying to avoid by using coax. Floating the braid at
the antenna feedpoint is virtually identical to an inverted-L.

Sounds like an inverted-V might work for you. Put a choke at the
feedpoint to help tame common-mode currents on the coax braid.

Mak:

Unless there is a lot of conductive material behind the brickwork [sheet metal or metallic chimney, or ...] the rising part of the inverted L near the brickwork should be no problem. I have tacked such risers along the tree trunks of pine trees and the side of concrete block and brick walls with no ill effects.

I would arrange for it to run an inch or two off the brickwork if possible, either with standoff insulators or what's often easier, simply pull the vertical run taught [that's what I usually do, unless the inverted L is hung in a tree which sways in the wind].

As Cecil [aka CAM] says the single wire riser is just as good, if not better, than a coaxial feed in which the outside of the braid/outer conductor will radiate anyway.

At least with the single wire riser/element for the inverted L you will not be fooled into thinking that it does not radiate or pick up unwanted noise.

It will radiate anyway from the outside of the coax.

With the single wire "L" riser/element you will tend to arange and dress it physically to make it a more efficient radiator, while with coax you will be lulled into thinking it doesn't radiate and dress it incorrectly, lying it alongside metallic stuff, etc...

Setting up as an inverted L will keep you focused on making the whole antenna an efficient radiator.

Good luck and keep us informed of your progress and efforts.

Getting on the air with an effective HF radio station is not as challenging as the antenna manufacturers would have you believe.

Do you have a good antenna tuner?

Reg:

Many have done that simple calculation long ago.

But then... just dismissing fractal electromagnetics as just some overwraught pompus posturing over superficial minor modifications of existing antenna structures, and relegating the fractenna postings to the delete file would have deprived the serious NG reader of hours of fun, comedy, excitement, and humor.

Where else can one observe an Ivy League Ph.D. squirming and fuming in such a delightful fashion and feel guilt free? Such behavior would not be tolerated at a Ph.D. thesis defense!

For many NGparticipants here the fractanal antics seems like a vicarious participation in the ancient and inhuman Roman "bear baiting" sport/amusement and without the guilt arising from baiting a poor caged dumb animal.

Here the "animal" has a Ph.D. and seeks to be baited. Simply for the pleasure of the NG participants.

Reg, would you really seek to end this "punch and judy" show?

Other than futile threatening gestures from the "bear" and largely phony threats from mercenary and possibly imaginary legal firms there is really no RSPCA to protect the bear and remove the NG participants "fun".

I for one would hate to see dear Dr. Chip, Ph.D. N1IR, NC, C++, Nathan Cohen, CTO, etc.... depart this NG.

For... without his sitcom antics, this NG would be but a pale imitation of it's current delightful incarnation.

And there would be no place for the world to learn "the truth" about fractal electromagnetics!

Thoughts, comments,

Peter K1PO

I cannot let the present stage of the fractal deer-baiting saga pass by without saying how much I have admired the great courage, ingenuity and enormous persistence displayed for several years by Fractenna, the solitary, isolated, Bambi ?) deer, in the face of what must have been the most prolonged and vicious attacks, from a more tormenting, slavering pack of wolves, smelling blood, sheltering behind numbers, than in any other campaign since the Internet began.

If any of you crowd of bullies should think Frac has been mortally wounded, think again. He's hardly been scratched. He's stronger because of it. You'd better retire to your corners, lick your wounds and nurse your guilty consciences. Either change tactics or the subject.

2318. Re: How Can I Match a 17M EDZ to COAX?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-17 00:00:00 UTC
From: k1bqt@aol.com
Message-ID: <20000917134202.03532.00000597@ng-fl1.aol.com>
Source record: 180562

> Would like to lay a 17M extended double zepp across the top of my roof, then feed with coax to the shack. How do I put together a matching section at the feedpoint?<

1. Don't put it on the roof, keep it well above the roof--especially if there's any wiring, flashing, or aluminum-backed insulation there.

2. Cut your radiators 5/8 wave per side and add inductors at the feedpoint to tune out the capacitive reactance (shouldn't take much--a few turns of miniductor). That should leave you with somthing approaching 100 ohms non-ractive at the center.

3. To feed it, make a line transformer using an electrical quarter-wave of 75 ohm coax. This will bring that 100-ohm feedpoint down to 50 ohms.

4. Wind the 1/4-wave hunk of 75-ohm coax into a choke balun at the feedpoint to decouple the outer shield feed from the balanced radiator.

5. Adjust coil inductance and element length, as needed, for minimum VSWR. Should be able get it flat.

Now the "tuner" is built into the antenna, and you won't ever have to mess with it again!

I'm sure glad they got rid of that nasty thing. Or at least the 1980's
russian version. I hated that blasted thing. It was generally assummed
to be over the horizon radar. I remember back when I worked 15m in those
days. I'd start working some good station, and that blasted peckerwood
would fire up. And the dang thing seemed to follow me everywhere I
went...:< MK

>actually examined a huge number of different designs.

Actually, I think that examining 10 random designs would let one say that 90% of randomly chosen designs will not be resonant.

Besides, one could say that 90% of randomly chosen lengths of doublet are not resonant on a particular frequency, too, especially if one did not define the limits of "resonance."

Hey guys, why not do it the easy way?
(Tongue so firmly in cheek that it hurts...)

Match-all Automatic Antenna Matcher is a solid state, non-resonant, broadbanded antenna matching device, independent of resonant lengths of radiating wire or elements to attain proper tuning and radiating results. Also unnecessary are activating rf input signals, control leads or DC voltages to instantly match virtually any antenna configuation on all HF bands including amateur and commercial, i.e. 2-30 Mhz. The input maintains a constant 50 ohms input impedance over the full frequency range. This device has been used by military services in spread spectrum applications and by commercial and fishing vessels. The unit is new-in-box, easy and ready to install.

And the bidding is only at $30.00 on E-Bay!

I think rather than such a huge tower, you should mount the DDS dish on your
roof, and cut a few trees around the house. Tell the other half that it is
for safety -- fire, wind, whatever, you should have a larger clearing around
the house itself.

With the dish hopefully 20ft up (near a peak) toward the north side of your
roof, the nearest tree will be on the other side of the house and yard.
Worst case the dish will be 1/2 the house plus the yard before the first tree.

Vlad,

No need for a 9:1 balun. I built one on a big core a few years ago, but find that the balun in my Ten Tec 229 tuner
is all I need. If you don't have one in a tuner then the W9INN remote balun will do nicely.

About two years ago the only line-of-sight I could find was the current mounting location. Eariler this year, I had my dish upgraded. An installer attempted to get a better line-of-sight. They tried for over 4 hours and still couldn't get a better shot than what I had.

I found it in my Radio Handbook handbook also (20th ed - 1978). Yes it says it is single wire fed. THis does present a problem.

However the Windom antenna on the www page I gave is feed directly from coax through a 4:1 balun. It soes seem to have SWR problems on 15m.

Since the guy on the www page I looked at has actually built one fed by coax and measured the SWR on each band I am happy to take his [measured] results as fact. The thrust of my question was along the line of radiation efficiency.

Does anyone know what sort of radiation effeciency can be expected from each of the antennas. If they are about the same I may simply convert my 80m dipole into a Windom.

I'd do the AM radio thing no matter where I moved. You don't need Distribution Lines to have electrical noise, just have a neighbor with a swimming pool or (don't ask me why)... but a funeral home across the street (at least i think they were the culprit). the Electrical noise was so bad that I had to get cabel TV to watch anything below channel 7. (then I moved next to the pool!!!) But that's OK, I installed a Sat Dish and it doesn't mess up the radio plus...it's an indoor pool and we have a key!

>send them any actual cases.

One of our local hams has 2.4 GHz wireless LAN products in use in his home,
and also 2.4 GHz cordless phones. Both use spread spectrum, of course, and
neither interferes with the other to a noticable extent. But, now comes wireless
broadband provided by AT&T (ex-Media One). Their provider site is less than
half a mile (line of sight) from his home. Now his phones suffer severe interference,
and the wireless LAN retry rate is noticably increased.

So far, no ill effects have been noted to his HF, VHF, or UHF amateur operation.
BTW his amateur operations haven't bothered his cordless phones or wireless
LAN or vice versa. If they are now bothering his neighbors who use the wireless
broadband distribution, no one has yet complained to him about it.

At the site of the wireless broadband provider are amateur radio repeaters
and television remote broadcast microwave links (for picking up the signals
of remote TV broadcast vans and relaying them back to the studio). On one
amateur UHF repeater (443.025), a buzz, which was not there before, can
now be heard under weaker signals. (Possibly a fundamental overload problem,
though a good pass/reject duplexer is used, and no current problems exist with
the over 100 other transmitters on the site, paging, cellular, LMR, LPTV, etc.)
This hasn't significantly impacted operation, but it is a nuisance that has resisted
attempts to suppress it.

Interference to the TV remote broadcast microwave link receiver is much more
severe. Hits can be seen periodically in the video, especially when using vertical
polarization. (The wireless broadband transmit antenna is vertically polarized.)
As a practical matter, the site is now useless for vertical, LHCP, or RHCP reception,
and has had to be restricted to only horizontal polarization to avoid significant
signal degradation. This is a fairly serious limitation because CP is the preferred
polarization to resist multipath (IE ghosting) of the signals from the remote vans.
Attempts to resolve the problem have so far been fruitless.

It would appear that wireless broadband may not be as good a spectrum neighbor
as has been portrayed, especially if one is near the source of the transmissions.
But at least the impact on amateur operations on popular bands seems to be minimal.

Source record: 180372

Hi,

I am considering putting up a short loaded dipole, primarly for 80m. It would be about 70 ft long (the max distance I can get across my house) and only a few feet above my roof. It will be in a shallow inverted V configuration, but not symetrical. One version would use one set of coils. The other would use 2 sets of coils and would provide operation on 40 and 15 as well as 80m.

Would there be much difference in performance on 80m between the two systems?

Should I use a balun? I will have about 125 feet of coax running along the roof and into the house.

Thanks for the advice...

What you say is true about inducted common-mode currents. Hopefully, the antenna system geometry minimizes these inducted currents. What I am referring to are the *conducted* common-mode currents as discussed in Roy's article, "Baluns: What They Do And How They Do It", in the ARRL Antenna Compendium Vol 1. With a dipole and no choke, if the impedance seen looking back down the outside of the coax shield is much less than the feedpoint impedance of the antenna, Ohm's laws says the current tends to *conduct* down the coax rather than into the antenna. In this case of conducted currents, the differential mode impedance can affect the initial conduction/generation of common-mode currents.

Seems worst case for conducted common-mode currents might be a full-wave dipole fed with 1/2WL of coax measured along the outside braid and using no choke. The differential current on the inside of the braid has the choice of becoming common-mode current into a high impedance antenna or onto a low impedance path to ground down the outside braid of the coax.

Not to mention any AM broadcasters within a half-mile of the house if 1000 kW
or less. Anything stronger is a problem for 1.8-2.0 and other HF ham bands.
I lived near an AM transmitter in Michigan and it even caused problems on the
CB band, I was only 300 yards away from the transmitter though.

2344. Stupid question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-18 00:00:00 UTC
From: oh3nx.nopespam.@sral.fi
Message-ID: <8FB389FFDjoenonenonecom@192.89.123.233>
Source record: 180426

Pardon me, but I got a stupid idea.

If we have a G5RV multiband dipole and the matching to a 50 ohm output transmitter coax is handled with a specific length of 300-450 ohm ladder line, can we apply the same matching approach to a vertical antenna?

Then we would have half of the "G5RV" standing up, the other half being represented by ground radials, and fed like G5RV, and voila, we would have a multiband vertical.

I would simulate this with EZNEC but I have only the trial version. Maybe I wouldn't need even EZNEC to find out why it wouldn't work if I was smart enough, but I'm not.

Any ideas?

There are two comments

1) Sounds like you are in the near field of the antenna; this is a major problem;
2) CHOKE THE HEXBEAM! I don't know what's on there now, but more beads will only help the choking. Also, choke at additional random lengths along the coax.

I'd pick up a little battery-operated shortwave radio from Radio Shack
or whomever, and take it along when house looking. Then you can listen
for noise at particular locations. Put each ham band in memory, and
zip through the bands, listening for noise.

(Whatever the radio costs, a bad noise problem could be a lot more
expensive to solve.)

I had one for years on a 50 x 100 urban lot, great antenna. 65 feet vertically about 20 feet from the tower in the back yard then 65 feet down to about the 40 foot level to a pole in the front yard. I built a simple (huge) motorized tuner for the thing which was at the base of the vertical run and was able to get a dead flat SWR anywhere between 3.5 and 29Mhz. while sitting on my butt in the shack. The "counterpoise" was simply a pair of 8ft ground rods in eternally damp soil.
>
I didn't win any contests with it but it was *very* competitive on 80 & 40 in the dx contests with modest power. The 80 & 40m portions of my very early 5BDCC were a cakewalk.

I accept ypur apology. Furthermore, to show my sincerity in this, I will be happy to discuss technical issues here, as time permits. If you can wait a few days, typically, for a reply I will be happy to respond.Needless to say we have other time sinks:-)!

My first comment/concern harps back to the spiral. Perhaps I misread your description, but at least in the context it was presented, it appeared that you placed it within an 1/8 wave by 1/8 wave form factor.

Given that it is in a MUCH smaller--and very electrically small-- form factor (5 inches for 20M wavelength) , I hope you will appreciate that it cannot radiate well, and that if you got a directivity of order 2 dBi, and an impedance of 30 ohms, that neither of these can help you in getting the observables of field strength and radiation resistance.

Steve--such spirals radiate poorly. I know this from experience with very similar designs provided me in the context of 13.56 MHz RF/ID.

If we can get some closure on this we can move to the MI2 "candidates''.

I, too, will keep this a 'ham' conversation and not construe this as some contention between firms.

Nice work on MI2, BTW.

Anyone can claim anything Terry.

The truth is, it's hard to tell the difference between a 5dB gain
antenna and a zero dB gain antenna unless signals are marginal or
noise is high.

On ten meters, or even twenty meters, it's pretty easy to work almost
every country available with persistance even with very low ERP. It
takes more time than station.

Taking an all-band country total made over years of time, and then
adding in a few ten meter contacts, is the most misleading kind of
subjective data. It worse than a ten-meter only country total, which
means next to nothing.

That wouldn't surprize me Jerry.

Here we have Dr. Chip, a self-proclaimed top-of-the-heap antenna
design engineer, not able to measure the output power of his PA.
Instead he asks others how much power he is running.

Pretty strange, isn't it?

If he borrowed the meter, he would have to understand how to use it.
If he understood how to use it, we would have to depend on him telling
the truth.

Even if we got past those two major hurdles, we still don't know what
his site looks like compared to other sites, or how propagation is at
any moment in time.

I suspect this is all a part of his clever trolls Rick, designed to
keep him in the center of the attention.

You could also construct a simple ground plane antenna using a SO-239
pannel mount connector and metal coat hangers. Solder an 18" piece of
hanger wire to the center post of the connector and attach four 19" pieces
(radials) to the base of the connector. Bend the radials to a 45 degree
angle down from the connector, connect a piece of coax between your radio
and the antenna and ...you're on the air!

Gary / N2UM

PS Don't forget to sand off the coating off the hanger wire ends so that
you get a good electrical connection.

Hi Bret,

It depends on what you like to do,and how those lines are installed
and maintained. If you like low band DXing, I wouldn't chance it.
I've had problems from lines a couple miles away.

If you only work 40 meters and up, you are probably OK.

Just remember if you have a problem, it can be next to impossible to
get it resolved.

Thread:

There were no threats that I recall, least of all "death threats", in any of the postings to the "open house" threads that I observed.

However, it may have been me that Chip is refering to and not Tom, since I jokingly referred to protecting and arming myself if I were to attend.

Since...

Immediately after Dr. Cohen mentioned in a post that the police would be there at the open house, I was totally surprised by the mention of police, and so... I opined in a subsequent posting that perhaps if I were to attend, I should wear a kevlar vest and carry my .357 for protection.

There were no threats posted to the NG that I recall seeing.

In fact, although I was in beantown on business last weekend, my dear wife advised me not to attend the open house out of fear of altercation caused by actions of Dr. Cohen. My wife often reads this NG over my shoulder and she is of the opinion that Dr. Cohen apparently suffers from paranoia and she opined that sometimes such sufferors might inadvertenly take actions that could harm innocent bystanders.

I wisely chose to take her advice and stayed away from the open house.

But... "death threats", I don't know where that idea came from???

2361. Re: NEC4 Model of Helically Wound Loop Re: MI2 Loop

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-18 00:00:00 UTC
From: VE9SRB <srbest@worldnet.att.net>
Message-ID: <1kqx5.20259$6f1.987201@bgtnsc05-news.ops.worldnet.att.net>
Source record: 180443

In a post Friday, Dr. Cohen made the following statements regarding my NEC4 analysis and the helically wound loop previously proposed as a small form factor design in the thread : $1000 Fractal Antenna Challenge.

>>> Dr. Cohen:
"He is clearly wrong. For anyone to say this, they cannot have a good handle on
understanding:

* mutual coupling;
* resonance;
* ohmic loss;
* radiation resistance;
* field strength.

Using words like 'directivity' and 'impedance' are cop outs that deliberately
avoid issues such as field strength and efficiency. I have no idea why someone
who claims to do antenna work would use NEC4 to get directivity rather than field strength, or quote an impedance rather than a radiation resistance (at the current max).

Field strength is the salient observable.
>>>

I use NEC4 to calculate directivity and impedance data simply because these represent the antenna characteristics in an ideal state. It is the logical place to start describing the antenna's performance. Practical deviations from this ideal state are numerous and include many factors such as ohmic losses in the wire, ground losses, SWR mismatch loss, matching network losses, dielectric losses (if the antenna if fabricated on a substrate), pattern degradation due to the surrounding environment, etc, etc., etc.

In my opinion, comparing the performance of the MI2 loop and another design in the ideal state (directivity and impedance) is valid because, for the most part, the practical limitations on the performance of each design is the same. The MI2 Loop and the Random Loop design both have the exact same wire length, wire diameter and aperture size. Radiation efficiency is simply a function of the ohmic losses in the wire and the radiation resistance. If both antennas have a similar feedpoint impedance, concerns regarding how the ohmic losses in the wire impact field strength (efficiency) are irrelevant.

>>> Dr. Cohen:
I remind everyone that this person formally told us that he had a 20

turn spiral that had better 'directivity' than MI2. Of course it has a far lower field strength because it uses 4 to 5 times the amount of wire!"
>>>

As for the previously defined helically wound antenna, Dr. Cohen is simply incorrect when he states that my proposed design has 4 to 5 times the amount of wire compared to the MI2 Loop.

>>> Dr. Cohen:
Given that it is in a MUCH smaller--and very electrically small-- form factor
(5 inches for 20M wavelength) , I hope you will appreciate that it cannot radiate well, and that if you got a directivity of order 2 dBi, and an impedance of 30 ohms, that neither of these can help you in getting the observables of field strength and radiation resistance.
>>>

First, if we model an antenna in NEC4 with zero wire loss, then the calculated feedpoint resistance is the antenna's radiation resistance (RR). Determining the loss resistance (RL) is simply a function of the ohmic losses in the wire. If we know the radiation resistance and the loss resistance, efficiency is easily determined from RR/(RR+RL). If two antennas have the exact same ohmic loss and similar radiation resistance, this discussion is irrelevant.

All issues on pattern shape and polarization aside, a helically wound design will not "radiate well" if it has a high loss resistance compared to it's radiation resistance. A low efficiency will typically occur under two conditions: 1) When the wire length is much smaller than the wavelength the radiation resistance will be low and the loss resistance will be a significant factor. 2) When an excessive amount of wire is used to fabricate the antenna, the loss resistance increases and becomes a significant factor.

A new helically wound design has been modeled in NEC4 under the following conditions - that it have the same wire length as the previously modeled MI2 Loop, the same wire diameter and the same aperture size. The helically wound antenna consists of a total of 64 turns (16 turns on each perimeter side) formed into a square loop having the same outside perimeter as the MI2 loop. The helical winding diameter is 5 inches. The pitch length per turn is about 4.95 inches on two sides of the perimeter and about 6.9 inches on the other two sides.

Note that I did not get the wire length and number of segments exactly the same as the MI2 because of the even number of turns in the helical winding sections.

Results are as follows:

MI2
Helical

Total Wire Length: 27.56 m 27.96 m
Number of Segments in Model: 500 548

1st Resonant Frequency (MHz) 15.749 17.657

Resonant Resistance (ohms) 28.4 47.9

Directivity (dBi) 2.14
2.31

2:1 SWR bandwidth on 50 ohms: 1.27% 2.83%

3rd Resonant Frequency (MHz): 28.65 33.35

Resonant Resistance (ohms): 19 39.2

Directivity (dBi): 4
3.91

Note that the feedpoint for the helical antenna was located in the center of one helical arm. If I move the feedpoint to a corner where a straight wire joins the helical elements, the first resonance changes to 17.83 MHz and 80.8 ohms. Note also that MI2 values change with moving feedpoint as well.

Note that lowering the resonant frequency of the helical design requires additional wire in the helical sections. However, lowering the resonant frequency to match that of the MI2 will not require 4 - 5 times the amount of wire.

If there is a question as the validity and accuracy of the NEC model with this configuration, I am open to discussion and correction as necessary.

Thanks for your time and patience in this one.

Mainly, "Or what?" I avoid the super high SWRs by making my dipoles 1/2WL at the lowest frequency of operation. In general, that limits the impedances encountered to a donut on the Smith Chart with SWR limits between 4.5:1 and 18:1 for 450 ohm line. I then install the 1:1 balun/choke at the current maximum point, i.e. zero reactance point. Thus, my 1:1 balun/choke sees a resistive impedance between 25 ohms and 100 ohms and functions accordingly. Conceptually, instead of bringing the balun to the antenna, I bring the antenna to the balun.

> The MFJs do have "baluns" and "open-line terminals" you can
> switch in and which supposedly properly feed balanced lines via their 1:1
> baluns. What's getting lost in the shuffle/losses if anything??

A lot of the MFJs use 4:1 voltage baluns which don't attempt to balance the currents. The main function of a T-Line balun is to minimize common-mode currents both on the coax side and on the balanced side. A balun operated far away from its design parameters will not perform that function very well. It's probably fairly uncommon for baluns to experience appreciable heat losses. The losses are generally of the nature of RF that doesn't make it to the antenna because of current imbalance. Some people don't consider unwanted feedline radiation as losses. I do.

The G5RV is a balanced antenna and the matching section is balanced.
IMO, it is virtually impossible to balance the currents on a matching
section of balanced line used with a vertical and ground radials.

From: jason_hsu@my-deja.com
Message-ID: <8q5gspqav1@nnrp1.deja.com>
Source record: 180446
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.antenna

My ground floor apartment is VERY RF-unfriendly. Even with my trusty ADI/Premier RD-98 antenna (a long, flexible 2m/70cm antenna for HTs), I need to use the roof of my car parked outside as a ground plane in order to transmit into the local repeater (which is a good 15 miles away).

Should I buy the $10 telescoping antenna that Radio Shack sells for 2m/70cm? It is quite cheap, and it should perform better than the flexible antenna when fully extended. A telescoping antenna is fragile, but I can still use the flexible antennna away from home.

Would it be possible for me to use a mobile antenna with my HT? (If so, I realize I would probably need to buy special adapters as well.)

Are there other options? A dipole? A wire? A small base station 2m/70cm antenna?

Should I select a 6m/2m/70cm antenna? In a few years, I might buy an HT that gets 6m or an HF rig that gets 6m/2m/70cm (like the Icom 706MKIIG or Yaesu FT 847).

Hi Bill,

There are some implementations of fractals that are susceptible to variations. One remarkable instance is my replication of the k2 that proved to be better than the original.

The original proved to be not so fully optimized as my replica and barely better than the simple Flying H that I designed that easily replaces either.

In another thread, Larry N0SA offers that he had a terrible time in building a fractal. Which one remains a mystery, in all likelihood it was the k2 or the Flying H (possibly the low Fractalope). Either show a very great variability in performance in relation to the proximity of earth. I included such instances as a service for those who cannot find elevation. Unfortunately, these Fragile Antennas require a considerable amount of hand-holding.

Some of these small fractal designs offered require the loss of earth (as they snuggle up to its deadly embrace) to offer a single unique characteristic while sacrificing every other characteristic by pouring power into the ground. The single characteristic's relation to ground proved to be intensely variable over the elevation variation of several centimeters! Imagine, a slight breeze could easily drive your SWR through the roof as the 'tenna sways. The k2 and its ilk prove to be the poorest "practical" design offered in a long time.

However, with any (this includes fractals) antenna, well away from ground (more than several centimeters), such variability rapidly drops away with increasing distance from ground. Note, there is nothing

remarkable nor fractal-like in any of this as the Flying H easily proves, it too employs the same ground "optimization." ;-)

Some may be confused by these shallow claims of a strict requirement for zero tolerance in geometry variation, especially when the fully qualified statement is split by over 100 postings across innumerable threads. For those who face such claims, if you are offered advice that a design is intensely linked to a rigid necessity of dimension, then you have an instance from Fragile Antennas. Surely a wonder in the lab, but as Larry N0SA has noted - a bitch to build and operate.

For those who wish to investigate practical fractal designs, my temporary page at:
http://www.seanet.com/~rwclark/fractal/Practical%20Designs.htm
offers some ideas. Over this weekend there were something over a hundred visits to the Fractalope alone.

Be advised that this design is the basic element, myself I would prefer the InVfracV which shows considerable gain over the other variants in the high band. However, it should also be noted that one variant will perform better than others depending upon band. That is, the FracT is considerably better in the low bands, but most designers will note that these variations on a theme simply reflect the reality of antenna design in general. There is no magic shape nor is there any panacea involved.

Be further advised that the maker of Fragile Antennas has condemned the data found in my pages - especially those pages that replicate many of these Fragile offerings as demonstrated by identical performance valuations to the original design. The implication of this condemnation is ironically reflective: condemning the original to damn the replica. As I offer EZNEC files for all correspondents to observe these issues for themselves, these aspersions are simply more instances in Fragile Antenna's kulture of denial.

I wouldn't worry about the "death threat" troll, either, Tom. According to the FBI, anyone is entitled to articulate any hysterical fear they wish (even Chicken Little). The agent went on to say that charges such like these are generally so easy to disprove, they'll likely never cause a problem for you in the future.

By putting it on the public record, however, they may cause a problem for themselves down the road.

As you know in most cases, I am anything other than a fractenna supporter. I will have to say that he has probably worked pretty hard for his position on the DXCC list. I have listened to him operate on 10 meters and he is a skilled operator.

In most other things in life he is a total putz, however as a DX operator I do have to throw kudos his way.

I reguarly use a dipole that is literally draped over the tree branches below my balcony. The untuned SWR on the dipole is 1.3:1. I run QRP and up to 50W. I have WAS and all over the world with good signal reports. The wire on the dipole is just insulated lamp wire. I have noted better signal reports from other horizontal antennas like inverted V's, and beams than with verticals, but I think that's only because we're polarized the same way rather than any deficiency with vertical antennas.
Just my 2 cents, your mileage may vary.

Anything works on ten meters, see QST a couple of months ago. There was a guy that worked WAC on 10 with a lightbulb mounted on a post. He had the coax choked so the only radiation was from the bulb and said it only took him 1 or 2 calls to get through. Almost identical to the fractal claims.

Those old baluns are the result of the old way of thinking that baluns
need to be 4:1. Most of that is changing now.

>mode currents both on the coax side and on the balanced side. A balun
>operated far away from its design parameters will not perform that
>function very well. It's probably fairly uncommon for baluns to experience

1:1 Choke baluns "care less" what the differntial mode impedance is,
as long as the wire doesn't melt or arc. You can, if you reach
impedances of a few thousand ohms, run into problems. Below that value
it's pretty easy to make a 1:1 choke balun work. No so with a 4:1 and
especially a 9:1 balun.

Even if you play with feeder length to limit differential mode
impedance, it is no guarantee you've changed the common mode impedance
favorably. In most installations common mode impedances are somewhat
moderated compared to differential mode impedances.

I'd always use a 1:1 choke type balun.

If the antenna has to be inside you might want to try a homemade ground plane hanging from the cealing. There are several ways you can go about this. Just strip about 19 inch of the shield of the coax off. Then find some stiff wire that you can hook to the shield at this point and bend about 3 or 4 pieces at an angle of 45 deg. to the ground.

Some have used magnetic mounts for the mobiles and put them on the top of a refrigerator or other mass of metal.

If you can get to the outside, then you can use any antenna that is made for the bands you want to use. Just because you have a handheld you are not limiated to a whip that is attached to it, but you can use any antenna type that you want to.

Steve,

It's became very plain that Dr. Chip misunderstands the use of
"radiation resistance".

There was quite a long thread on this, where he stood alone with his
opinion. No amount of reference material was good enough. Dr. Chip
said Kraus and others didn't know what they were doing, or that they
were "waffeling".

When he uses that term, he means the resistance at a current maxima in
the syatem, regardless of how many other current maxima's there are.

For example, he would consider the radiation resistance of a folded
dipole four times that of a conventional dipole without apparent
regard to the fact loss resistance when normalized to the same point
in the system and using the same step-up ratio would be four times

higher.

He also only considers FS at the maximum point "important" and somehow
equates that to "efficiency".

I hope understanding how he uses the terms will help you understand
what he is saying. I'll try to offer shortcuts for you, so you don't
have to spend weeks out what he is trying to say.

>In my opinion, comparing the performance of the MI2 loop and another design

>(efficiency) are irrelevant.

Not in all cases. It depends on how the losses are distributed in the
systems. Different antennas with similar feedpoint resistances and
conductors can have greatly different losses.

>>>> Dr. Cohen:
>Given that it is in a MUCH smaller--and very electrically small-- form

>losses in the wire. If we know the radiation resistance and the loss
>resistance, efficiency is easily determined from RR/(RR+RL). If two
>antennas have the exact same ohmic loss and similar radiation resistance,
>this discussion is irrelevant.

Those losses have to be normalized to the point where radiation
resistance is taken, otherwise they are meaningless. The formula
Rr/(Rr+Rloss) only works when the resistances are normalized to the
same point in the system by whatever "transmission line" effects are
involved in the antenna. If the antenna had uniform current
distribution, then that formula would work without normalizing the
resistance loss to the point where radiation resistance was taken.

>conditions: 1) When the wire length is much smaller than the wavelength the
>radiation resistance will be low and the loss resistance will be a
>significant factor.

I think what you mean there is spatial area is small compared to the
wavelength. Ten feet of wire in a one foot area does not have the
radiating efficiency of ten feet of wire occuplying ten feet of
spatial area.

>A new helically wound design has been modeled in NEC4 under the following
>conditions - that it have the same wire length as the previously modeled MI2
>Loop, the same wire diameter and the same aperture size. The helically

>loop. The helical winding diameter is 5 inches. The pitch length per turn
>is about 4.95 inches on two sides of the perimeter and about 6.9 inches on
>the other two sides.

I would expect that to work more or less about the same as an antenna
with sharp zig-zags, or better. Sharp bends have no special magic over
gradual curves.

Ben,
I guess it depends on how large of a capacitance hat you
need. One, two or three stiff wires radiating from the coil
whip junction will work. Vary the length of the wires to
change capacitance, or add a few more.
You can use, pie plates, pizza pans, etc, just up to your
imagination (and what the 'significant other' will put up
with.

2385. Cheap MW antenna (low band)

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-18 00:00:00 UTC
From: Frazier <frazier@flex.com>
Message-ID: <39C6B6C9.94754706@flex.com>
Source record: 180467

I'm located on the big island of Hawaii, and desire improvement of my MW (AM radio) reception. Since I fairly recently moved here, I've not had much chance to take the time to upgrade my ticket, so am not operating on the HF bands.

This message, however is for the purpose of increasing reception of american AM stations, both reasonably local, and from the mainland of North America.

Cost is a big issue, so I need to keep the costs down.

I live on a 1.6 acre parcel, with a two story house (sith about 2600 Square feet of sheet steel roofing). There is ample room for a pretty long wire to the north or west, some to the south, but almost none to the east or northeast.

First choice is to improve reception towards the north or northwest (around or over the volcano) for Honolulu stations. (The big island of Hawaii is the southern-most island of the Hawaiian chain) Second choice would be to improve reception of stations on the mainland, which is east-northeast from here...

A tuned loop might fill the bill, but I'm not too sure where to look first. Most of my listening is after dark here, so day time reception isn't as much an issue.

I'm using a commercial HF transceiver as one receiver (Signal One) and a Sangean ATS-909 portable (which also has an external antenna jack).

I'd appreciate any ideas on what path to take...

Rick,
First, let me say that you live in a terrible spot for MW DX'ing,
and I think you should trade places with me!
If that won't 'fly', then let me say you have a number of very nice
options. If it is at all possible, I'd take advantage of that metal
roof with a vertical of some kind. Or, you might try for an 'over the
pole' long wire(s). If trees are situated right, you could try
directive
arrays, wire beams, etc. There is no 'best' antenna, just antennas
that work well for your location and ($).
If all this gets to be too much for you, I'll leave the 'trade'
option open....

Dear Peter, I'm afraid your sort of reaction is a common occurrence - if I'm not wholely with you then I must be your enemy.

People should be more certain of their motives - after experiencing disappointment in one direction they should try not to vent their aggression on the next imaginary victim who exposes himself. (Now THERE's an opportunity for sex-deprived contributors.)

I am not anybody's second. Neither am I a character assassin. I try to give credit where credit is due. And I may be an iconoclast when pompous icons are concerned. Technical icons.

But most times I just let things pass when they become personal. It was probably a mistake responding to your suggestion and question.

On August 16 th, I offered to pay the postage for Chip
to send his K2 Fractal Flyer antenna to a ham who had
no antenna. Chip's response to that ham was:
"The K2 Fractal Flyer still looks like your best option."

It has been one full month, and as all can see, Chip
did not respond.

My offer is hereby withdrawn.

Hi Chip--

>With my 520 watts, and the info available on the web on my antenna, what IS my EIRP?<

Your "520" Watts may actually be something very different. If you'd like to borrow my Bird 4391, pehaps you could measure (rather than "calculate") what your PEP output is. I'd be happy to send it to you--it's very easy to operate. As it is, how could you have a clue? Fact is, you don't, so why should I?

>Assume, say, a 1 dB insertion loss for the coax.<

Why would I do that? I don't know and neither do you. Have you measured it?

>...you made a serious gaffe in determining the OUTPUT power of an SB220.<

You are correct (not that "serious gaffes aren't made on here). When I make a mistake, I'm usually very quick to admit it so people on the newsgroup are not misled. How about you? This size of my wiener doesn't depend on being right. The size of everyone's learning depends on my readiness to be wrong.

The key factor is your ground conditions. How could you possibly know what you've got, given the irregular terrain of your site. Fact is, you can't. Like the insertion loss, you're assuming something based upon some arbitrary abstraction. So you're asking me? I can easily admit my "gaff", but what would be the point of trying to caluclate your ERIP. That would be an exercise in nonesense--as is your challenge.

I did try to point out that your output (which you seem to want to minimize) might be more than you think. I think Tom might have "amplified" upon that. The offer is open--I've got the right slug to make the test and I'm willing to share. Once we know what's coming out of your amp, then we can work on the rest of what is a very complex problem.

Just an RF choke may not work, you need a RF choke AND a capacitor, I assume this is low band, guess 75 meters?

100uh and .01 cap to ground.

What panel?

Have your isolated the zones that may be causing this.

I had a problem with my napco panel and the caps and chokes did the trick.

Also is the panel grounded? If it's UL install, you can't pull the ground, but if it's not try pulling the ground and trying another ground point.

Now that was rude of you to say this about me. You don't even know me.

>Dino- You must be one of the most naive people alive. If you buy any of
>chips lies and obfuscations, you must be pretty new on this NG. For some
>specifics, see interspersed comments below.

I snipped the rest of your comments Bill. You have good points and I'm not going to argue with you about them. We agree that Tom is a superior designer.

As far as Chip's design, I can understand why he is secretive. Just ask K6STI and WA8DED. Both have been ripped off by the "Amateur Community". If his claims of working DXCC (if I remeber that correctly) is true, then obviously his design works. Personally I don't like the fractal antenna. But I don't like Cushcraft either and they seem to work well too.

I was asked for my "comments" and I gave them. Please don't attack me for having my opinions...especially when asked to give them.

Thanks Bill and 73!

I just talked to a trucker this past week and he has a Band Hopper antenna.
I never saw one before. What he liked was the fact that the BAND HOPPER
does NOT change length when being tuned. This is important especially for
a trucker! He gave me their web address and I check them out...

http://www.bandhopper.com/

Personally, I like the High Sierra antenna and will buy it for my Suburban...

http://www.hsantennas.com/

But your best bet would probably be the band hopper because of its fixed
height. It can handle 600 watts.

Being notably lame technically in this topic area perchance you can straighten me out. Not-so-hypothetical scenario: 100 or so foot random length dipole/vee intended for use on 80-10, random length open wire feedline of random characteristic impedance. As you well know the feedpoint impedances can run from R2-j10 to R3500+j2500, the usual. I've done/tamed several of these and they work just ducky - as long as (in daze of yore) I stood on my head and cobbled together ungainly, inconvenient coil-swapping parallel-tuned tank center-link-fed balanced tuners and diddled the taps. So along comes the ferrite core balun craze. Per your post above, are you saying that any decent 1:1 balun/choke can transform the balanced feedline with an R(x) + j(y) impedance into an unbalanced feedline with an R(x) + j(y) feedpoint impedance no matter what? Or what?
>
Fact is that there are a gazillion very convenient to operate wide-range unbalanced tuners out there, the assorted MFJs being prime examples. To the best of my knowledge there are no real catalog-number balanced tuners out there today. The MFJs do have "baluns" and "open-line terminals" you can switch in and which supposedly properly feed balanced lines via their 1:1 baluns. What's getting lost in the shuffle/losses if anything??

No Rick--

That's not good enough. I made an honest--and within practical limits--
accurate estimate of the output power , feed system insertion loss, and antenna
field strength.

NOW:

YOU tell us the EIRP. Otherwise you have hit us all with a barrage of
histrionics, meant to anger and incite. That is EXACTLY what we DON'T need in
this new age of FCC compliance.

So, what's my EIRP? Assume reasonable practical uncertainties and get it.

73!

Peter, I gather from your comments that Fractal antenna provide a great deal of fun off the air and in the NG for those in the know. May be it is rare to work a Fractal equipped station? The station I worked clamed to be using a two element Fractal quad. He took the time to claim that his small antenna's performance was comparable to a full sized quad. Now I wish I had taken more time too speak with him about his antenna. This NG has certainly peaked my interest in the design.

Another peculiarity- the "antenna" in question has two power cords that must be plugged into outlets that are at least 10 (if I remember right) feet apart. This implies to me that they are using the house wire for something.

Any Ideas about this feature?

Bill

Thomas Rauch, W8JI, has continually made every effort to lie, harass, and even threaten me. Last week he posed a death threat on this NG against me. I am in serious fear of this person and have taken the proper steps to protect myself and my family, which even included certain understated precautions here at the open house.

Two weeks ago I canceled a public ham talk in Portland, Maine, because he made public assertions that he would be present, and I was not given sufficient information how my safety could be assured. It is exactly W8JI's bizarre and threatening behavior that made me promise my wife that I would not give ANY MORE public talks to ham radio operators.

Understand what this means: someone who has championed and pioneered a new technology--of great interest to hams-- will NO LONGER speak to hams publicly. Imagine the kind of unrelenting harassment by W8JI and others that forces someone to make such a decision!!

One of the actions includes initiating the process of civil suit against Mr. Rauch in his home state of Georgia.

Nathan Cohen, Ph.D.

Did I miss something again-? I thought I had read everything posted here, and I do NOT remember a death threat. I'm sure I would have remembered one if it was from Tom, or any of the regulars. I remember when Chip dodged the club meeting, and I remember all his talk about police at the "open house", but not anything serious.

Can someone give me the date and time, so I can read it for myself?

Date: 2000-09-18 05:41:48 UTC
From: Terry Redding <terry@oltraining.com>
Message-ID: <39C5AB18.3CA288CD@oltraining.com>
Source record: 180420

David, thanks for the comments. BTW, I just paid a visit to your web site. Very very impressive. Worth a re-visit and taking a bit of time to see how you built the pages. I am typing this response while loading the web cam page. I also have a web cam at http:/www.olt.net/W6LMJ.

Back to the quad/loop. I have never used one - so bow to the experience of anyone who has. But I have observed to in operation. The first was used by Mike Stalter, Pebble Beach, California. An elmer of mine who took the time to introduce me to SSB operation on ten meters ground wave while I was stationed at Fort Ord, California in the mid 70`s.

Mike had a daily schedule with a ham in Japan on 15 meters CW. His modest choice of antennas was either a mono band 3 element yagi on 15 meters or a 15 meter loop (he called it a single element quad because it started out as the driven element of a quad - but he never added the reflector). He commented with some surprise that often the loop out performed the 3 element yagi, especially when the band appeared noisy.

My other experience - third hand again - was with an antenna used by WB2UJL - Ernie Miles, one summer. Ernie planned to operate from the Houston, Texas area for a three month period a few years ago and was concerned about having a consistently good signal for a 20 meter net he and I participate in each Sunday. Ernie's normal antenna is a 2 element GEM quad.

Ernie likes to experiment and is fairly deliberate about his projects. So, during the period leading up to his trip he bought a 30 foot pushup pole, balun, and built and refined his loop while still at home until it was a consistently good performer. His finally design for his 20 meter loop is my starting point for a loop on 40 meters. His final design was a loop, fed at the top, that hung down in a diamond configuration. As simple to erect as an inverted vee, it appeared to work well.

He operated weekly from his daughters QTH in Texas. She lived in a neighborhood with deed restrictions and so he put the antenna up for the nets, and took it down after each net. He operated with 100 watts using a TS 870. On our net was Fred Naylor, VK3AQN, who routinely checked in long path. Ernie had the distinction of being one of the few stations on the net able to work Fred consistently.

Much of what I have read here on the list indicates that both Mike Stalter and Ernie Miles enjoyed more success with their loops then they should have.

I am fortunate to have a tower with an inverted vee for 40 meters. Armed with the information gathered here I plan to put up a series of loops and compare them to the inverted vee. Hopefully I will learn something along the way, and end up with a better 40 meter signal to the mid west and west coast then I currently am able to achieve with the inverted vee.

Hmm, the web cam images seems to be black. Must be near real time. This is being typed at 1:36 a.m., from West Palm Beach, Florida. I will try it again in day light. Now I am curious to see if the web cam shot is from one of the towers in your images.

Thanks again for taking the time to comment on my loop project.

In general high lines are not nearly the problem that old, grubby distribution lines can be. Assuming they are the usual 3-phase layout, only the unbalance current shows up in the near field anyway. Given the catastrophic nature of any failure and the numbers of people affected, your friendly neighborhood Reddy Kilowatt bunch is not going to let maintenance slip.

Beg, borrow, buy, don't steal, a battery powered radio, preferably shortwave capable and find out. Carry it with you and check the vicinity.

Personally, I have run 2, 10, and 15 mobile from a parking lot virtually under a 245kv line and listened to my el cheapo Grundig YB305 with no ill effects, to the radio reception at least. Until the glow dies down, it is hard to sleep :-)

Do the radio thing anyway; goofy noise sources are everywhere. And try to stay away from 400k ERP television stations and 100k FM if at all possible.

Enjoy being a homemoaner.

> indoors.

Is your window clear glass or is it aluminized to reduce sunload? If it's clear glass, you might consider taping a full wave loop to the window glass. You would need a separate loop for 2m and 440 but that shouldn't be a problem. You can use thin uninsulated copper wire taped to the window for minimum visual impact but the adjustment may be a little difficult unless you have suitable test equipment. Monofilament fishing line stretched from the window frame can be used in lieu of tape if the RA has a problem with adhesive tape on the window. Another option is to use conductive burglar alarm tape which can be purchased at Radio Shack along with an appropriate adhesive and connectors. The larger conductors will result in a system which is less critical to adjust and somewhat less sensitive to objects moving around in the immediate vicinity.

Depending on the window size and orientation, you can also experiment with phased arrays of dipoles or loops if you need more performance or are simply interested in the design and implementation of more complex antenna systems.

David,

I have (or perhaps had) been considering the same single-loop design. I am about to erect a 60 foot tower, and thought I would install a pair of loops, 90 degrees out from each other, and feed them from the bottom. I'd then planned to design a switch box to select any two legs, hoping that I could produce a little gain and directivity on 30 meters.

From your response, I will be just as far ahead building two inverted vee's, and switch selecting between legs of them.

Rick, KD6QZD wrote:
"First choice is to improve reception towards the north or northwest
(around or over the volcano) for Honolulu stations."

First step is to determine which stations you can hear best now, however poorly or infrequently. How about shortwave? Those can be heard on the floor of the Grand Canyon where no medium wave stations are heard.

Are the medium wave stations you hear in Honolulu or are they in mainland states?

The stations you can hear now may be the ones to spend time on to improve reception.

With wavelengths in the hundreds of meters, horizontal antennas long enough and high enough to give the gain of a h-f directional array are usually too costly. Vertical arrays are costly too. So, what`s left? For medium wave there are super loops and long low wires.

Have you considered a satellite dish?

Super loops are available. Loop gain is nearly multiplied by the permeability of the loop`s core.
So, a big long powdered iron core is good bet. Less turns are required for the needed inductance and a high Q is possible.

A wire as long and as high as possible pointed in the desired direction is another good bet.

Best regards, Richard Hsarrison, KB5WZI

Cecil, you know how much I dislike having computer programs thrown at me. Eznec is wrong. And I wouldn't argue with Walter just because my thumb happens to be just a teeny bit smaller than his.

SWR on a short high-Zo line has little to do with it. On 80m, what really matters is line loss, loss in the tuner, loss induced in the house structure and wiring and loss induced in the ground. And Eznec can't tell you any of that.

From Klines brief description of the antenna passing within a few feet of the roof of the house it can be assumed the feedline would be quite short. In fact, if the shack is in a bedroom the loss in the feeder will be small compared with the other losses mentioned.

Loading coils for 80m, the only band on which they might possibly be of use, would have a degrading effect on higher frequency bands which Kline specifically mentioned.

Adding 10, 15 or 20 feet of wire, towards the ground, from the dipole ends would overcome your objections to high swr.

And personally I prefer any loading coils to be very-low-loss, home-brewed, complete with alligator clips, in the form of a tuner, next to the transmitter. Oh yes, musn't forget the smoke alarm.

I am using the Alinco EDX-2 which appears to me to be the SGC-230 with some of the brains removed. It tunes on command, not automatically.

I have been using it to drive a balanced feed line for over 2 years. Last time I mentioned it, several posters took issue with that configuration. I am not using any kind of balun, and I have the "ground" side grounded to the station ground. I wound an open air 1:1 balun and tried it out just to see if it changed anything. Only difference I noticed was a loss of received signal strength on the lower bands. I removed the balun the day of the experiment.

Initially I had the tuner under the desk and the feed line coming into the shack. Last year I moved it to the outside and added rf beads and torroids on my control line and coax. I have a large open frame relay that removes the feed line from the tuner and grounds the feed line whenever station power is off.

I am using a 100 watt Alinco DX-77T and the feedline is TV line.

Good luck
John KA9CAR

One of the most popular replacement antennas used on consumer type
radios and tvs over the years has been the good old
wire coat-hanger. People use them and get better reception
than if they used nothing at all, but no one has ever argued
that coat-hanger antennas are optimum in any sense other than being
readily available.

A true statement that ignores the fact that INTERPRETATION of the natural laws does change, and frequently. Add to this the ever-present problem with verbal communication, and definition arguments, and the immutability of Natures laws is not really the question.

Greetings Group,

While you are trying out those antennas, you might find this software useful. :-)

Just released, a new "downloadable" software product named "ID Wizard". It is QSLware, meaning it's basically "free". The only catch is we request users send an email with comments.

Here's a little info about the software.

"
ID Wizard is an ID timer with system clock setting and miscellaneous tools.

Tools include:
Notes - a full-featured "text" editor
Calculator - with "tape" display
Net Utility - Trace Route, Ping and WhoIs
Time setting via the net with "Simple Network Time Protocol"

The clock face is fully customizable. User can select a bmp picture for the face, plus select clock hand color and more.

Screen shots, more info and download from:
http://www.taborsoft.com/softstuff/idwiz/
"

Also available, a fancy ID timer, as QSLware. It's named NERDAlert 2000. It's presented in a more "fun" spirit. You will find it a very capable ID timer. If you wish to look at it:
http://www.hamtools.com/nerdalert/

Regards,
Jim

I'd like to caution once again against using Chip or any other single person or small group to be representative of Ph.D.'s in general. Or against stereotyping any group, for that matter.

Some of the regular and most helpful and knowledgeable posters on this group have a Ph.D. degree. They don't belong in the same group as Chip, even though they might have the same level of degree.

>Tom Donaly KA6RUH

Hi Tom,

You neglected that with that particular style of antenna, the most
popular optimization employs crumpled (dare I say fractalized?) tin
(aluminum/aluminium) foil balls at the ends.

Every kid in America (before cable) learned optimization first hand.
It is only because of cable that this art has died and discussion of
the optimized coat-hanger has fallen into decline.

2420. Re: Cheap MW antenna (low band)

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-19 00:00:00 UTC
From: Frazier <frazier@flex.com>
Message-ID: <39C7A264.F85F763B@flex.com>
Source record: 180282

Thanks for the responses. (public and private)

I can hear Honolulu station at 830Khz. I can also hear a number of mainland stations like 1090 and rarely 810. In all cases (even Honolulu, which is about 200 miles away) I have nearly no reception during the day, and significant fading during night listening. There are several other stations I'd like to get again, so I don't want to limit myself to a specific frequency. Also, even some of the local stations are occasionally weak in the daytime, with frequencies of 620, 670 and 850Khz. After my escape from the major rat race in California, I wouldn't trade living here without a real good living, but it'd be nice to have better AM reception.

I've seen a picture of the Kiwa Loop (air core) and it looks interesting, but I can't handle the $400 price tag. I've a limted budget for this project, though a decent amount of time for experimentation. Parts can be a problem over here, as there are no available surplus stores or ham swaps, so most of my parts will need to be ordered mail order, or wait for my next visit to California.

I'd be interested in building a loop, either air or powdered iron core, but don't have a good idea where to start looking for details (wire size, number of turns, capacitance to add, etc.) Also, pointers to available core material would be nice.

I do have a device called a select-a-tenna (541-M) that I bought a few years ago which helps some. It provides a pre-selection function by mutual coupling with the internal loopstick of the portable receiver, and can be used to connect to the antenna terminals of either radio. I'm guessing it's not really much more than a loop with a capacitor across it.

Satellite? I've a C/Ku band dish (aka BUD, Big Ugly Dish) but the program sources I'm trying to receive aren't on the sat. audio channels.

Long wire is somewhat limited as to direction and height due to the relative lack of trees.
I could get about 150 feet of wire in the air to the south, or 200 to the north, but the maximum height would be about 25 feet or so, with a big droop in the middle because one end would need to be secured to a tree, and even with a pulley and weight mechanism to keep the wind movement from killing the wire, it would probably droop quite a bit. I may put one up just to see how much it helps, even if I

I want to make sure credit goes where it should. The first time this was brought to light in the amateur literature, to my knowledge, was in Walt Maxwell's article "Some Additional Aspects of the Balun Problem", in QST, March 1983. My Compendium article adds to what Walt presented.

Hi,
I am in a similar situation, but am on the top floor of my dorm. I went with a 300 ohm twin-lead j-pole inside of pvc and it works great. It is easy to get into the local repeaters and the swr is about 1.4 to 1 on both bands with 10 watts, 1.2 to 1 with 5. Only bad part, if you don't have a air wound coil, it will get into the speakers of nearby radios. Currently it is hanging iverted infront of my window and nobody seems to care, they can't see it, hi. Here is a web-page to the plans, and everything should be available at the local hardware, except coax and connectors. These are the plans that I used.

http://www.thedragonmaster.com/j-pole.html

-73's- and good luck.

EIRP is the effective isotropic radiated power sometimes commonly referred to as ERP. It is a reference indication of how much power a system (not antenna) "effectively" radiates as compared to the power the system would radiate if an isotropic antenna were used as the system antenna. EIRP is determined by multiplying the power delivered to the system antenna (SWR mismatch loss included) by the antenna gain. The resulting quantity from this multiplication is power. EIRP is not determined from power to an antenna times peak field strength. Radiated field strength being defined in V/m (I have never seen antenna gain referred to as peak field strength). I am not sure what units power * volts/m yields.

I did not see the posts where someone stated that directivity and gain were the same thing. This would only be true if the antenna had 100% efficiency. I did however see the posts where the performance of two antennas were compared and directivity was one of the comparison factors. In this comparison both antenna had virtually identical radiation and loss resistance so a comparison of directivity was an acceptable indication of relative performance.

Look at the ham page

http://www.fractenna.com/ham/hampage1.html

and be a goody dooby and tell us what is wrong or misleading or just plain inaccurate about the performance the relative advantages or anything else. Go ahead and do everyone a favor and tell them what is wrong.

From what I've seen of other ham antenna web pages this is perhaps the best documented antenna from a performnace and modeling standpoint on the web.

Dr. Cohen should be getting major kudos for helping hams out. Not stupid idiotic crap like this from a few jerks.

Cecil, fine, he doesn't need any lossy loading coils,
weighing down the antenna, reducing effective height, and on
the whole being nothing but a maintenance problem.

I have recently received a suggestion from an Italian
amateur that I should include in my antenna programs the
weight of the copper wire needed to wind the computed number
of turns on my loading coils and traps.

If I could find room on the screen I could very well do
that. But then I would receive extra requests from deprived
US amateurs for the weight and amount of sag to be presented
in lbs and inches rather than kilograms and cms.

There's no way I can win !

Nothing wrong with 16 feet. Can can we ignore a change to 6
feet plus 2 feet + 2.387 inches at 3.76174 MHz.

But my figures apply at 20.0 degrees centigrade I
understand much american data is at 25.0 degrees centigrade.
Fractal reports and investigations don't bother to mention
ambient temperatures. So it can't matter very much. But we
must not junk american data just because of this minor
reporting inconsistency.

587/freq in mhz=length in ft. Multiply X 12 for inches. For 146 mhz the whip needed would be 48.2 inches.
BTW, the formulas for the loading coil if needed are 165/freq in mhz X 6.26 for a non grounded coil. For a grounded coil would be 305/ freq X 6.26 . Answer is in microhenries needed. But yours should work fine as is. I just threw in the coil formulas in case someone tries to make a 5/8 ant. MK

2439. HF link coupled feed question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-19 00:00:00 UTC
From: Bob <xyz_p15218@flash.net>
Message-ID: <%yQx5.2032$864.87790@news.flash.net>
Source record: 180301

Link coupled HF antenna tuners drawings usually show a split variable capacitor in parallel with the "secondary" coil feeding the feeders. The rotor of the capacitor is shown grounded in many schematics. I have tried my system both ways...with the rotor grounded and floating. It seems to make no difference and only a miniscule difference in the SWR. The antenna is a 40 meter dipole fed with twin lead and used on 40, 30 and 20 with the same link circuit, using different taps on the coil. Anyone know for what purpose the rotor might be grounded??
Thanks

Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.dx,rec.radio.amateur.misc

Brett:
The correct answer is:
Any location where any power line will be visible from the uppermost part of the antenna structure is too close.

The comment that distribution lines are more likely to cause radio noise than transmission lines is correct. All cases of noise can be mitigated, but some are too expensive, and often the downsized utility has no one knowledgeable enough to locate the sources, anyway.

Pay the utility which serves the area a visit and ask two questions:
1. Do you have TVI mitigation capability?
2. Does this capability extend to shortwave?

If they can answer either question without having to go into an engineering conference, you will be miles ahead.

More people probably understand the Beverage better now, than 50 years ago.

>The military book, "Electrical Communications Systems Engineering", does >not include any puffery for promotion. It was issued, not sold.

As are $1000 toilet seats, in the military. As was Star Wars.

>Relying on TESTIMONIALS can get you in trouble. The authors of the War

Amen. That's why I go by practical experience and the experinence of others.

NEC agrees closely with the results everyone sees also.

>This War Department book is old, but the laws of nature have not changed >any more than Ohm`s law has changed.

Just like the 1/4 wl long folded dipole TV antennas? If it's in a book, it must be right...eh?

Seriously Richard, your book may say otherwise but that isn't how it works. If you doubt that, ask other people with both Beverages and full size verticals, or look at other references.

Rick, KD6QZD wrote:
"I can hear (a) Honolulu station at 830 KHz."

My charts show KIKI in Honolulu at 250 Watts, non-directional, with a probable unobstructed service radius of about 75 miles. Rick is 200 miles away and has an obstruction near his site and in the path. Rick could also have nighttime interference from WCCO in Minneapolis which runs 50 KW non-directional.

Rick can sometimes get 1090 KHz from the mainland. This would likely be KING in Seattle, which runs 50 KW.

Rarely. Rick gets 810 KHz. This would likely be KGO in San Francisco. The problem with this 50 KW station would be its north-south directional array designed to cover the mainland`s Pacific Coast.

620, 670, and 650 KHz are other possibilities, but they are relatively low powered stations in Hawaii. 620 is a regional channel usually limited to 5 KW. 670 and 650 are former 50 KW clear channels now shared with lower powered regional stations. 670 KHz is occupied by WMAQ in Chicago, the former clear channel station. 850 is occupied by KOA in Denver.

KNBC in San Francisco on 680 KHz may be another possibility using a selective receiver and a directional antenna to eliminate interference from the "local" 670 KHz station. KNBC is 50 KW and non-directional.

I used to listen to WCBS, New York from Lisbon, Portugal with good results, nightly. I used a Beverage antenna at about 12-foot elevation supported on poles. It was very long. I had a 500-acre site.

What Rick wants to do can be done, but it isn`t that cheap and easy for every day results.

Best regards, Richard Harrison, KB5WZI

>
>Have you used a 10 M - or other ham band - fractal antenna?
>
>> Dino
>>
>

It seems to me that Dino recognizes that the on the air success, documented technical info, and fact that many hams have built and are using these antennas indicates this is so.

Is there some counter-data you wish to present that the 10M FQY does NOT work as described? Please post your data on a web page and I will be happy to link and critique.

The only data I have seen to the contrary are:

1) W4JLE's hoax from Sept 1999;
2) W8JI's hoax--in which he claimed the fractal was so inefficient that it burned his grassland from starting a fire.

There ya go: ham radio showing it's best face to the public.

Also, as Phil asked you earlier, what is it about the web page that you take exception to:

http://www.fractenna.com/ham/hampage1.html

Either stop complaining or give something concrete that can be discussed.

Hey, even the best of us are seen as idiots by someone, sometimes. On occasion, I think we all deserve the title. I sure know I have put my foot in it once in a while. :-)

> EIRP= power to antenna times peak field strength (call it directivity if you
> wish, some herehave been using the term wrong abd calling GAIN the same as
> DIRECTIVITY).

Yes, you are correct that gain does NOT mean directivity, although one cannot have gain without it. One could have an antenna that was very directive, but very lossy, thus had no gain. A beverage receiving antenna or most small loops are good examples.

However, EIRP is not the ratio between power and peak field strength. One cannot directly create a ratio out of applied power to an antenna and a measured or calculated electric or magnetic field. Even in calculating the power density (if you are in the far field) or the plane-wave-equivalent power density if you are in the near field, you cannot easily calculate EIRP from applied power and the measured or calculated power density at a given point. If you stipulate far field conditions, the calculation can be done *if* you know the specfic distance you are from the antenna, but I have never seen EIRP defined as the ratio of applied power to power density; I don't even want to work out the formula. :-)

In essence, EIRP is the ratio between the applied power to an antenna and the power that would have to be applied to an isotropic radiator to create a field strength or power density of the same value, at any far-field point that is in the direction of maximum directivivity from the antenna.

A subtle difference, but an important one to those that want to correctly use the term "field strength." Many hams say "field strength" when they mean "power density;" I know I once did, having been called on the carpet at an RFI talk for saying that, in the far field or an antenna, the field strength decreases as the inverse square of the distance (1/D^2). My statement was incorrect; in the far field, the field strength (ie, electric or magnetic field) from an antenna decreases in inverse proportion to distance (1/D). The power density, or square of the field, decreases by the inverse square.

> If you wish to see how the EIRP figures into galactic SETI and the best way to
> establish a link, , then I will send you a preprint in a few weeks to

W1RFI,
> if requested.

I certainly would not mind seeing the article. I generally skip right to the chase and use the path loss formula, antenna gains, feed line losses receiver noise figure if dealing with a true line of sight path. If there is known path attenuation, I can add or subtract that in, too.

> Isn't EIRP wonderful?

It certainly does have its uses. If EIRP is known, for example, one can easily calculate system losses, too, by just assuming the transmit antenna to have 0 dBi gain. One can also, using the same assumption, calculate field strengths, power densities, etc., in the far field from an unknown antenna. EIRP will also give you some idea of how well you will be heard elsewhere as compared to a lower power and, if the transmit power is known, let you calculate the gain of the antenna. One can also plunk EIRP into some of the propagation modeling software (my favorite free one is at http://elbert.its.bldrdoc.gov/hf.html, get the HFWIN32 software; it is great!). I guess you takes your choices; you generally need at least two parameters, ie EIRP and applied power, or applied power and antenna gain, or EIRP and antenna gain, EIRP and distance, etc., to be able to do anything useful. It is sorta' like the relationship between receiver noise floor, dynamic range and intercept point. You need to know any two of the three parameters to be able to characterize the receiver.

> Sure hope someone can show I am using it right:-)!

If I can find the time, Chip, I can take a look, but I imagine you are. Your statement relating it to field strength was certainly intended to be a simplification. I am merely choosing to expand upon it.

Actually, EIRP is the power at the antenna times the gain of the antenna
referenced to an isotrope. If you prefer dB's, it's dBm + dBi.
Hope this helps. 73,

> resistance so a comparison of directivity was an acceptable indication of
> relative performance.

If I were comparing antennas that I believed would be virtually identical loss, I would probably model them as lossless, just to get a fast idea of the relative gain between the two. I just ran an EZNEC model of a 20-meter Yagi with 1" diameter elements, comparing the gain with zero loss elements and aluminum elements. The difference was 0.02 dB. If I were using EZNEC, I would probably just use the wire loss function and be "real," but if I were modeling in "native" NEC, I would skip it; it is too much work for 0.02 dB, and I expect that, unless one antenna being compared is expected to be lossy, the actual difference between the two would be less than that.

It is kind of like the old question; imagine you are standing 10 feet away from the most beautiful woman in the world, and every minute, you halve the distance between you. How long will it be before you meet? The correct answer is not, "You will never meet." The correct answer is that after about 30 minutes, you will be close enough for all practical purposes. :-)

From: Arthur Unwin <aunwin@fgi.net>
Message-ID: <39C7F7DA.6AFA4965@fgi.net>
Source record: 180316

Gentlemen,
Discussions in an older Antenna Handbook regarding
stacked antennas state that they are not as good as
monobanders when looking at rear radiation but do point
to the advantage of the 'noise shielding' provided by the
upper antenna in inclement weather.

Has there been any info published as to why this is
so? Guesswork?
Have any methods been used to simulate this shielding
effect with single antennas?
Large capacity cap on tower top to ground get the job done?
Comments appreciated

> At it's primary design frequency, the classic Windom operates as a
> horizontal half wave dipole.

I stand mostly corrected. I had based my statements on the windom on what I recall Jerry Hall, K1TD, telling me about some of the modeling he had done years ago. I just ran the EZNEC model of a windom and, broadside to the antenna, there is significant horizontally polarized field. In the exact circumstances I chose, the V component was down about -15 dB.

> The single wire vertical feedline operates substantially without standing
waves

Appears to be true, when the antenna is cut to the formula and operated at resonance. When I had a half-wave feeder, though, the "SWR" on the line jumped to about 3.5:1 when I modeled the Windom cut for 3.75 MHz on 3.5 MHz or on 7 MHz. I didn't experiment with the tap point much, though; I just used a 130 foot flat top, tapped 47 feet from one end. Didn't try other bands.

> The operating impedance of the feedline is in the neighborhood of 600 -
900 ohms

The model predicts 508-j412 ohms for a quarter wave feeder and 233+j209 for a half-wave feeder. This would still make the statement generally true.

> making the ground losses associated with the feedline generally small
compared to the the losses
> associated with the 1/4 wl high horizontal dipole radiator.

I am not sure what losses would be associated with the quarter wl high half-wave dipole radiator. With w pretty good ground (a 0.25 lambda buried vertical wire), EZNEC with the NEC-4 engine gives me about 5 dBi gain for the Windom, straight up, *off the the end* about 1.25 dBi gain for the Windom broadside and 6.29 dBi gain for the half-wave dipole, now modeled over average ground. I did see some intersting patterns wrt hte ends of the antenna. :-)

> The Windom is a mechanically robust, elegant design suitable one or two band
> operation, but probably not a good choice in a cluttered environment
> where the common mode feedline current is likely to pick up stray RFI.

Yes, ALL the current on the feedline, about 2 A for 1 kW input on 80 M, is common-mode. :-)

By adjustment, do you mean that the tap point is adjusted? That could explain some of the differences.

> The primary downside of the classic Windom is that it is a narrowband
> antenna with a high impedance feed. If not adjusted properly, or
> operated more than a few percent off it's design frequency, the vertical

Just as a few points of clarification, it would be equally valid for any other expression of power, such as dBW, etc. It is also the power fed to the antenna terminals, not the power of the transmitter, unless you also factor in feed line loss.

Also, that dBi reference is for the gain of the antenna in situ; ie, over ground, with any other attenuations factored (loss through buildings, etc.)

As a last point of reference, over "average" ground, a half-wave dipole up a half-wavelength has a gain of about 7.8 dBi. Very interestingly, this is a gain of about 5.2 dBd. So a half-wave dipole over real ground really does have a gain of 5.2 dB compared to a half-wave dipole. :-) This is, of course, because the term dBd is a half-wave dipole in free space. This causes no end of confusion when some compare an antenna gain to a dipole at the same height and call the result dBd. The terms dBi and dBd really are mathemetical constructs.

What an unnecessarily complicated job you are making of it.

Download in a few seconds program ENDFEED from my website.
Not zipped up. Run immediately. No six week course of
instruction on how to use it is needed. Input data on a
"what-if?" basis. Get yourselves into the 21st century.

Just enter simple antenna and ground system dimensions. It
will not only tell you, within milli-seconds, antenna
feedpoint input impedance, R and jX , it will also tell you
the L and C component values for the antenna-transmitter
matching network.

It was only idle curiosity, Chip; if you have a reason to want to keep it a secret, I really don't mind.

> Or is the ARRL particularly interested in the screenname of
fractenna@aol.com
> for some reason?

> What reason?

It was only idle curiosity, Chip (I assume NC is Chip, but if there are multiple users sharing the same AOL screen name, please accept my apology.) Why would you think that my question could represent an organizational interest by ARRL? The normal usenet convention is that people do not post the views of their employers; their participation is personal. There is no reason that does not apply here, Chip, and to help make that point, I deliberately do not include ARRL in the Organization: line or in my sig. The fact that this post does originate from arrl.org is probably found in some of the headers, but I make no bones about that either way.

It would be no more correct for you to assume that ARRL has an interest in the screenname fractrenna@aol.com than it would be for people to assume that Fractenna feels it has somthing to hide by your not answering my question.

I must say that your reaction to my question was a bit unexpected. If this is a sore point with you, I will not trouble you with it again.

I'd never really heard of that on stacked antennas, but I guess it could work much the same way as the "static hats" that you see on the top of some verticals. I remember alot of older 5/8 CB ground planes used to use these. How well they work, I dunno, but I think they do help a little. A large ball would be better to my way of thinking. Unless maybe they are refering to a "non static related noise. MK

Really. I believe W1RFI was the first to ask for it. How do you find
it believable that people are responding to posts they don't read?
Also, please consider the fact that it takes no more time to answer a
question than it does to make insulting and condescending remarks to
them.

Let me ask a question.

When you calculated efficiency, did you plug a conductor resistance
into NEC and let it normalize the loss resistance to the feedpoint?

What I'm trying to ask is how you determined the amount of feedpoint
impedance due to radiation resistance and the amount due to loss.

Ed- Dont worry, Chip does this often. When He feels like being nasty or vulgar, he posts as "Phil". It is not dignified for an assistant prof at a small Boston Metropolitan college to indulge in such, so he uses the "nom-de-crap" of Phil.

It is a matter of record that he has used MANY such alter-names, but only "Phil" has had much continuity. In some cases, he has actually carried on cross-postings with himself, apparently to get questions he expected but were not forthcoming.

If you dont believe me- ask Tom, Richard, Peter, or any of several other regulars here.

:
:Look at the ham page
:
:http://www.fractenna.com/ham/hampage1.html

I did
:
:and be a goody dooby and tell us what is wrong or misleading or just plain
:inaccurate about the performance the relative advantages or anything else.
:Go ahead and do everyone a favor and tell them what is wrong.

He compares apples to oranges. Comparing a dipole with no
reflector/director to a yagi fractal antenna is like comparing a bb
pistol to an AR-15; They're kindof the same thing, but not really

:From what I've seen of other ham antenna web pages this is perhaps the best
:documented antenna from a performnace and modeling standpoint on the web.

Not really. Like has yet to be compared with like.

:Dr. Cohen should be getting major kudos for helping hams out. Not stupid
:idiotic crap like this from a few jerks.
:
:Phil
:de N1ZKT

Chip might have something with the particular arrangements of these
fractals, however, he has yet to provide comparative data that
actually means something.

Let's have some data comparing, say, a 10 meter Moonraker 4 with a 10
meter FQY, or a single element fractal dipole with a standard dipole,
or a single element 1/4 wave fractal vertical with a single element
1/4 wave standard vertical antenna. Then we'd have some meaningful
comparisons to judge from.

Just my two cents.

I wrote 620, 670, and 650 KHz are other possibilities.

850 is occupied by KOA Denver and I thought Rick, KD6QZD said it was also a local frequency he said he could hear weakly at times during daytime hours.

I may have misread something. 650 KHz is shown on my old FCC charts as KPOA Honolulu at 10 KW non-directional. It shares the frequency with WSM an old clear channel 50 KW in Nashville and several other regional stations the FCC has allowed to co-exist on the former clear channel.

The good news is that the FCC chart shows KPOA`s coverage area just reaching the shores of the big island of Hawaii. That would mean that with some effort 650 KHz from Honolulu might be received in Rick`s location.

Tom, W8JI wrote: "Nonsense. Everyone who uses a Beverage understands they have negative gain."

According to Terman in his 4th edition of "Electronic and Radio Engineering", page 871, the gain as a power ratio (not db) of a nonresonant wire 2 wavelengths long is 6.5 when compared with an isotropic radiator. (a power ratio of 4 is 6 db and a power ratio of 8 is 9 db)

If this wire of 2 wavelengths is brought close to the ground it will experience loss imposed by the soil`s imperfections. The soil is neither a good conductor nor a good insulator. The severity of the loss depends on the exact soil composition and how near the wire is placed to the soil. The soil will eat away at the gain and directivity of the wire.

Some Beverage antennas will retain some gain when close to the ground. Some will not. It is simply a matter of whether the difference between the antenna gain and the ground loss is a positive number.

Best regards, Richard Harrison, KB5WZI

You might find these links helpful.

http://home.inforamp.net/~funk/page6.html

http://www.carcanada.net/dx/donloop.html

http://www.mindspring.com/~brucec/amloop.htm

http://user.netonecom.net/~swordman/Radio/shloopant.htm

This one deals with longwave....below the AM broadcast band....but has some good tips for you... http://lwca.org/library/rcvg-lib.htm

Radio Australia's Medium Wave Loop Antenna Plans
http://www.carcanada.net/dx/loop1.html

I found these in a few minutes by entering BCB Loop antenna in the Alta Vista Search Engine.

Final suggestion I can offer is the radio....I don't recall your mentioning what receiver you are using, but I can recommend the GE Superadio 3 as being a good performer for the money spent....and it also has terminals for external antennas to be attached, so the loops work well with this combination. Here are a few links to the Superadio 3 sites. If you look around on the net, there are places where they sell factory refurb and repacks for about $40....a particularly good deal for the dollar spent.
http://www.grove-ent.com/RCV5.html

This radio is not perfect however, and while it has very good performance for the dollar, you will find the reviews and FAQs for the Superadio at:
http://www1.shore.net/~dmoisan/faqs/superradio/gesr_faq.html

I'm sure you will get some excellent infomation from these sites, and the people who run them. This should keep you busy on the web for awhile!

I feel that if you only want 80 and 40, you're best off with the
Butternut HF-2V. I have found it to be 2 S units better then the
HF-9V on these two bands.

To educate yourself on verticals, I'd go to Butternut's web site.
They have a complete set of manuals, which have very good descriptions
of radial systems which should answer all of your questions.

I also have an MFJ-1798 (one of those "radial-less half-wave"
verticals that covers 80 through 2 meters). It is truly a compromise,
but does work if you can't have a radial system. It also feeds back
a LOT of RF into the shack, so you need to buy a Radio Works Line
Isolator and a couple of Radio Shack 8' grounding rods to get rid of
this RF with the MFJ or Cushcraft.

Hi Richard,
the form still exists. Around here (California), it
has degenerated into straightening out the hook, bending the
rest into a diamond shape, and then attaching the result to
what's left of your car's radio antenna which had been lately broken off
by the fellow whose parking spot you took. I remember the aluminum
foil. I used it myself, on occasion, but could never quite get
the hang of it.

Nope, not true. Let's say such an antenna has a feedpoint impedance of
6k ohms. That's an SWR of 13:1 using 450 ohm ladder-line and the impedance
at a current maximum with an SWR of 13:1 is 35 ohms resulting in a 50 ohm
SWR of 1.4:1. Making the dipole 1/2WL on the lowest frequency of interest
avoids a multitude of problems.

The problem with dipoles less than 1/2WL is that the resistance goes down
and the reactance goes up causing the SWR to increase without bounds.
For dipoles of 1/2WL or longer, the resistance and reactance track to
a certain extent so the maximum SWR has an acceptable upper limit.

> > In general, that limits the
> > impedances encountered to a donut on the Smith Chart with SWR limits
> > between 4.5:1 and 18:1 for 450 ohm line. I then install the 1:1 balun/
> > choke at the current maximum point, i.e. zero reactance point.
>
> 80-10 including the WARC freqs??

Yes, definitely. The impedances at the transmitter vary between 25 ohms
and 100 ohms on all bands 80m-2m which gives 50 ohm SWRs less than 2:1
on all HF bands plus 6m and 2m with no tuner required.

2481. Building helical antenna to span 470 to 850MHz (UHF TV)

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-19 00:00:00 UTC
From: Robert Casey <wa2ise@ix.netcom.com>
Message-ID: <39C83BD0.36C1443B@ix.netcom.com>
Source record: 180343

Any ideas on how to build a helical antenna that can cover this
wide of bandwidth? 470 to 850MHz (UHF TV channels 14 -69).
Looking at the ARRL Handbook, 1978 edition, page 635 is
a helical antenna for 432MHz. "Each turn is a wavelength long,
with a pitch of 1/4 wavelength". Now could I build a helical
with varying diameters of the turns? Imagine I have a cone
that I wind the turns on, starting at a 4 inch diameter and
tapering up to 8 inches. And the wire of the antenna spirals
around the cone, the turns getting bigger as the cone gets
wider. And then the base of the cone sits on a screen mesh.

Would this work, give me some directionality and gain,
and bandwidth? Figure it would feed 75 ohm coax to feed
the TV set UHF tuner.

It was a joke, Reg. Did you see the smiley face?

> But I do see what you have in mind. Another 16 feet on each
> end would take the antenna into the G5RV region where a
> tuner might be dispensed with and the system tuned up by
> adjusting the length of the ladderline.

Actually, the G5RV length has too high an SWR to use the line alone for tuning on 75m. It takes a parallel capacitor to twist the impedance to 50 ohms. That's why I use a 130ft dipole.

> There's a blind operator near me who has a low dipole. It is
> resonant somewhere between 80 and 160m. The dipole centre
> passes by the shack (his bedroom) window. Feeder length is
> about 6 feet to the tuner. He has no worries about swr on
> the feedline which is open wire spaced at 5 inches.

And thus his tuner has to do all the work. My transmission line does all the work and I don't have to spring for a 500w tuner.

> I hear there's a continuing drout in Texas. Is it something
> to do with global warming ? It can't be doing your ground
> system much good.

We got no rain during July and August but have gotten over three inches so far in Sept. Signals are definitely better after a rain. And this planet had global warming long before manmade greenhouse gases. The temperature S/N ratio is so low we won't know one way or the other in our lifetimes.

Korinna & Peter wrote:
> How should I install a wire to get best results on as many as possible
> bands.

I helped a ham with such an antenna and he was very pleased with the results. He had an A-frame attic and installed large end hats on his short dipole. Worked like a charm for all-HF-band operation. Here's my previous posting on the subject.

You know how top hats work on mobile antennas? Well they can work just as

well on attic antennas. In fixed font, it looks like:

```
/\ /\

/ \ / \

/ \ / \

/ +--\------------------FP------------------/--+ \

/________\ /________\
```

The hardware cloth triangles are cut to occupy the available A-frame

space and mounted on stand-off insulators. The ends of the dipole are

attached to the center of the hardware cloth capacitive hats. The

dipole feedpoint is in the center. If this is to be an all-HF-band

antenna, the feedline needs to be ladder-line.

The butternut hf6 if you want dx.

It's one of the cheapest.

No loss due to traps.

No earth loss due to missing ground plane or ground wires. (You have to make a proper ground wire system, or when it's in the air a radial system.) Remember that every vertical must HAVE a radial system. Those sold without are expensive dummy loads :-)

Almost full antenne lenght on every band giving the highest possible radiation resistance. On 10m its working with the full 29ft/7.9m (equal to 3/4 Wawelenght) On a trap vertical the effective lenght is typical a 1/4 wavelenght.

Mogens

Monster Tower!

http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=438969842

This is the "Hummer" of freestanding towers. To call it a "crank-up" is a misnomer. All you have to do is flip a toggle switch and sit back in your patio chair and sip your beer. You will have plenty of beer left over once the 1HP motor finishes smoothly raising the tower!

I am selling at considerable loss as I am contemplating a move and removal will simplify the sale of the house. (unless of course you are looking for a 3BR 2BA ranch with 2 car garage on 2 acres in a semi rural, antenna friendly subdivision? If this is a case, drop me a line, maybe you can get a "free" tower, installed!.)

>The Windom is no better nor worse than most other sorts of
>simple wire antenna in that it radiates nearly all the power
>which is put into it - even on 15m. You've been listening
>to the wrong old-wives' tales.

I respectfully disagree. The Windom functions as a loaded random wire, worked against earth ground. The single-wire "feed line" is actually the part of the antenna that does the majority of the radiation. The "feed line" generally will not radiate as efficiently as would an antenna at the same height as the top section, due to losses in buildings, etc.

The Z at the end of that "feed line" is difficult to predict. This can generally be matched with a good antenna tuner, though.

The antenna's performance also depends on ground losses. This can be somewhat offset by the use of a ground radial system, but that seems like a lot of work to use an antenna that is generally used because it appears to be easy to build and use.

If it were me, I would elect to feed that top section with ladder line, fed either at the center or offset, and use my antenna tuner to bring it all to resonance.

Message-ID: <HPGx5.7668$ap5.133276@news6-win.server.ntlworld.com>
Source record: 180388

I've looked at various YAGI designs for 70cm work. I downloaded and ran "YAGI41" and have been able to modify designs for other frequencies. However I'm getting stuck on the impedance matching systems:
Delta, T and folded.

1) is the spacing distance on delta etc. the centre to centre distance of the edge to edge distance
2) the capacitance giving when matching, is this in series or parallel to the coax.
3) So should I try to minimise or maximise the capacitance?
4) On the folded dipole option, I assume that the capacitance will show 0 where an inductance is needed.

If anyone can help or has any links to information on suitable YAGIs I would be grateful!

<snippage>

Yes, they can, Gary, but your post illustrates very well that those problems are dealt with effectively in the commercial world. The original premise of this modified thread was that the broadcasters were being allowed to get away with exposure faux pas while hams were being required to comply. In reality, most commercial stations don't have any problems at all, and those that do, generally deal with them.

>Sb220 on 10M...

You may want to post that question on .misc or on one or more of the contesting or DX reflectors. My '220 has been out-of-service for a while.

The SB-221, a '220 that had no stock 10 M operation, was Product Reviewed in March, 1980. The unit ARRL reviewed had been modified for 10 meters. In the lab tests on 10 m, ARRL found the following:

Mode DC input (PEP) PEP RF Output
CW 1000 W 500
SSB 1900 1000

The CW input was limited to 1000 W to stay within the spec of 1000 W max DC input.

The complete review is available for download on the ARRL members-only site.

Try mounting it on the front fender using a mount that goes inbetween the
hood and fender. Feed the coax thru the firewall.
Larson has a dual band that works well or there are small dual band rubber
antennas around. I have a Comet SBB-2NMO 19" Dual Band that works well and
is very durable and can handle up to 60 watts. The longer antennas are
going to give you better performance. But if you live in a area with lots
of repeaters you can get away with the rubber Comet.

Source record: 180395

Kline,

Better performance than either of the loaded versions will
be obtained on all bands, 80 to 10, with a simple dipole of
random length (eg., your available 70 feet), fed with an
open wire (1 inch or greater spacing) line or 450-ohm ladder
line, also of random length. Simplicity = Efficiency and
easy maintenance.

Suggest you invest in feedline and tuner rather than in
suspended fixed-value loading coils. Or wind your own
low-loss 'loading' coils and locate them in a home-made
tuner in the shack where the weather can't get at them.

Connect the feedline wires together and use the system as a
T-antenna on 160 m tuned against ground. The ground being
the domestic plumbing system plus a few random-length
shallow-buried wires in the garden if you have one.

Nope; I don't need any pats on the head OR back; but go take a look at the elevation power pattern comparison to a dipole (Fig 3) .

http://www.fractenna.com/ham/hampage1.html

I am a bit amused that HAMS assume I am the village idiot. Some anyway.

EIRP= power to antenna times peak field strength (call it directivity if you wish, some herehave been using the term wrong abd calling GAIN the same as DIRECTIVITY).

If you wish to see how the EIRP figures into galactic SETI and the best way to establish a link, , then I will send you a preprint in a few weeks to W1RFI, if requested.

The paper was given at a conference at Boston University and described at:

http://www.spaceviews.com/2000/09/article3b.html

The paper is by Cohen and Hohlfeld and is:

"Mutual Figure of Merit In an Interstellar Intelligent Communications Link"

The important results from said paper is that : 1) the link will be at microwave; 2) small dishes on receive (such as done by Seti League folks) are a waste of time;
3) the transmitter aperture, if doubling as a power collector (i.e. an aperture engine) has a 4th power of the diameter dependence in the MFOM.

Basically this shows that ad hoc descriptions of using the microwave window, andthe ad hoc assumption of using large dishes are formally and globally correct--without any biases on modality; solid angle covered; or wavelength to be used.

Isn't EIRP wonderful?

Sure hope someone can show I am using it right:-)!

Hi Kline--

>It would be about 70 ft long...only a few feet above my roof...a shallow inverted V....not symetrical.<

Don't know height of house, but can you pick up any more wire length by drooping the ends (say 10 or 15 feet per side)? That will help your bandwidth.

<...use one set of coils...(vs)...2 sets of coils and would provide operation on 40 and 15<

Wouldn't a pair of 40-meter L/C traps allow you to work both 40 and 15 while inserting minimum inductance in each leg? Also, may be able to use 40-M coils with capacitive pigtail to optimize 15? (think I saw that in one of the antenna books).

> Should I use a balun?<

Always--and especially in your situation.

concerns
> >regarding how the ohmic losses in the wire impact field strength
> >(efficiency) are irrelevant.
>
> Not in all cases. It depends on how the losses are distributed in the
> systems. Different antennas with similar feedpoint resistances and
> conductors can have greatly different losses.
>

I assume that when you state "similar feedpoint resistances" you are
referring to the total resistance which is comprised of both the radiation
resistance and the loss resistance. In general, your statement is
absolutely correct. In the case that I am describing, both antennas have
similar radiation resistance and similar loss resistance. As a result of
this specific condition, the concerns regarding a comparison of efficiency
are not an issue.

>

> I'm puzzled by the 5 inch + 1/8 wl at twenty meters statement. What is
> he saying??????
>

I am not sure either. These statements do not describe the geometry of the design discussed in the $1000 Fractal Challenge thread. My description was not very good either so I can see how he became confused. The alternate design (this thread) is described in a bit more detail. The NEC file is also available for anyone interested.

> spatial area.
>

This is correct. The efficiency of the antenna is a function of both ohmic losses and the radiation resistance. Changing the antenna geometry will impact the radiation resistance and hence efficiency. Other factors to consider are the antenna's directivity and ultimately, the antenna's SWR mismatch loss.

I am not really sure why Dr. Cohen is so focused on efficiency and "field strength is the salient observable". There is a lot more involved in determining the field strength than knowing the antenna efficiency. Two antennas can have the exact same efficiency and entirely different gains and radiated field strength. Two antennas can have the exact same gains and different efficiencies. An antenna with a gain of 20 dBi can be less efficient than an antenna with a gain of 2 dBi. Reflector antennas (dishes) are a good example.

Some general "Antenna 101" comments: Antennas are not power amplifiers. Antennas cannot radiate more total power than that which is delivered to their input terminals. Antennas are directional amplifiers focusing energy in one direction more so than others. The directivity of an antenna is an expression of how much the antenna focuses energy in one direction wrt an isotropic radiator. The efficiency of an antenna is measure of the power losses in the antenna. Gain is determined from both the antenna's directivity and its efficiency.

The efficiency of an antenna is a function of the antenna's radiation resistance (how much power is delivered to the antenna for radiation) and the antenna's loss resistance (how much power is delivered to the antenna and is lost as "heat"). Typically, when an antenna is electrically small, its radiation resistance is very low and its loss resistance makes up a significant portion of the total feedpoint resistance, hence efficiency is low.

Determining the field strength as the "salient observable" requires additional information as this is really a system issue. If you know ONLY the gain of an antenna you cannot determine radiated field strength in V/m. To determine the field strength, we need to know how much power is delivered to the antenna. To determine this, we need to know the antenna's SWR mismatch loss wrt the feed cable and we need to know the losses in any antenna matching network. These are significant factors because an antenna may have high efficiency but it may also have high SWR mismatch losses and as a result, the radiated power (hence field strength) is low.

The point is that this is a more complex issue than knowing antenna efficiency.

What's the feedpoint impedance of a half-wave folded monopole?
If the physical length including VF is 1/2WL and grounded at one
end, it is hard to visualize how the impedance at the other end
could possibly be any lower.

The FQY's on-the-horizon orientation, the area's irregular ground characteristics, the radiator's unusually low mounting height, plus the extremely uneven terrain and presence of large obstructions at Ledgewood Place are all givens--observed by any who attended the N1IR open house.

Is it your position that, under these most unusual site conditions, your far-field ERP is easily calculated and constant for all headings--something like a microwave dish pointed straight up into deep space?

I dunno, Reg. EZNEC sez the SWR will be almost 200:1 on 80m.
He could wind up trying to match two ohms or 90k ohms. IMO, the
G5RV length of 102ft is just about the minimum acceptable dipole
length on 80m. Walter Maxwell suggests that 3/8WL minimum is a
good rule of thumb.

He could have a 70ft horizontal section and have 16ft hanging
down vertically on each end. But if the dipole has to be 70
ft long, I think loading coils would work better for 80m
operation.

I have a J-pole home-brewed from TV twin-lead that works amazingly well. I use it when I'm travelling. During my last trip I was able to hit a repeater nearly 10 miles away with my HT on it's low power (1W) setting. This was from inside a hotel room with the antenna hanging from the bedpost. I like it because it's very handy for travelling and provides significant gain over a rubber duck.

I was just going through the manual for my new SGC-230 tuner (replaced a 230 PRO) and noted that on page 25 of the manual they show using the 230 feeding a center fed antenna through a balanced feedline. Elsewhere in the manual, they make the point that you must not connect a feedline (assume they must mean a coax feedline) to the output of the tuner. Have any 230 owners fed balanced antennas via a balanced feedline? What's the effect of using a balanced feedline in this fashion, where one side is effectively grounded?

I forgot to add - if possible turn the ends of the dipole sideways or downwards through 90 degrees to increase overall wire length. This modification is a very effective way of improving multi-band performance in a limited space.

Another disadvantage of loading coils and traps - their weight very much increases wire sag and decreases effective antenna height. Of all antenna characteristics on the lower HF bands, height above ground is the most important parameter.

Tom, W8JI wrote:
"Relying on one source, especially a Military publication from many years ago (and especially when dozens of other sources conflict with that data), can get you in trouble."

It is important to consider the source. None are infallible. But, I recall reading of the WW-2 efforts to produce the military book in a civilian book published about 50 years ago. Authors of the civilian book were Timbie and Bush, if I recall correctly.

The military book, "Electrical Communications Systems Engineering", does not include any puffery for promotion. It was issued, not sold.

The forward is simple: War Department, Washington 25, D.C., 25 April 1945.

TM 11-486, Electrical Communications Engineering, is published for the information and guidance of all concerned. By order of the Secretary of War: G.C. Marshall, Chief of Staff.

Relying on TESTIMONIALS can get you in trouble. The authors of the War Department book were America`s leading scientists. Contents were backed by tests, measurements, and experience. The purpose was survival in the most perilous times. Further the purpose was "---for the use of staff signal officers---."

This War Department book is old, but the laws of nature have not changed any more than Ohm`s law has changed.

Best regards, Richard Harrison, KB5WZI

> balanced feedline in this fashion, where one side is effectively grounded?

The reason that SGC doesn't want one to connect a feedline to the output terminals of the SGC-230 is that the voltage *can be* sky high. It doesn't have to be sky high but it can be. For instance, using a 14ft mobile whip on 75m, the whip base voltage will be enough to cause coax to arc over if used on the output. That's why the SGC-230 doesn't have a coax connector on its output. This sky high voltage condition *usually* doesn't exist when using balanced feedline. So the apparent contradiction is context dependent and can be summed up as:

Avoid using a transmission line on the output of the SGC-230 anytime the resulting output voltage would cause the transmission line to arc and/or melt.

When using balanced feedline on the average fixed ham antenna, the output voltage from the SGC-230 is no higher than from an ordinary tuner. Therefore, the same matching techniques can be used, which includes a balun/choke on the output of the SGC-230. However, caution must be taken to ensure that the balun doesn't see the maximum voltage of which the SGC-230 is capable.

Why don't you just build a little ground plane vertical on a coax receptacle? Do one for 2. Another for 440. Just get out your trusty soldering iron, some wire, and build the little suckers. Hang 'em in various parts of your apartment, and see what happens. And if that doesn't work, then look at some kind of "gain" antenna.

From: Stan Olson <solso@advancenet.net>
Message-ID: <39c77b43@news.advancenet.net>
Source record: 180413

I live in the first floor of a dorm and I was wondering if there was any sort of antenna I could build or buy to improve reception / transmit on 2m/440... Outside antennas are not an option, so it has to be completely indoors. I've got an Icom W32A with a Comet BNC24 whip antenna on it right now. It works fairly well, but I was curious if there was anything else better to try other than walking outside and trying there, hehe. Would a mag mount dual band antenna work indoors? (would I be harmed by the RF?) If anyone has any ideas, please let me know. I bought the 'Stealth Antennas' book by ARRL, but it was disappointing with it's lack of indoor options. Thanks!

> top section, due to losses in buildings, etc.

At it's primary design frequency, the classic Windom operates as a
horizontal half wave dipole. The single wire vertical feedline operates
substantially without standing waves and is responsible for around ten
percent of the total radiation. The operating impedance of the feedline
is in the neighborhood of 600 - 900 ohms making the ground losses
associated with the feedline generally small compared to the the losses
associated with the 1/4 wl high horizontal dipole radiator. The Windom
is a mechanically robust, elegant design suitable one or two band
operation, but probably not a good choice in a cluttered environment
where the common mode feedline current is likely to pick up stray RFI.

> The Z at the end of that "feed line" is difficult to predict. This can
> generally be matched with a good antenna tuner, though.

When the system is properly adjusted, the feedline operates
substantially free of standing waves and the impedance at the
transmitter end of the feeder will be between 500 and 1200 ohms,
primarily dependent on wire size. Significant deviation is a sure sign
the antenna is not properly adjusted.

The primary downside of the classic Windom is that it is a narrowband
antenna with a high impedance feed. If not adjusted properly, or
operated more than a few percent off it's design frequency, the vertical
feeder does indeed become a significant part of the radiating system.

If I didn't join the self help group I would post the following:

On this NG we have:
Chip, NC, Dr. Nathan Cohen pH.D., Freak, Frac, Phil, JoeO, Cohendog, Fractenna, etc.
They can be heard at radiostation N1IR using freak-frac antennas. Often they have runs, which they post here to annoy people. Their antenna claims are shocking, like fecal flyer antenna, Quad is a Yagi, Russians use repeaters to jam broadcasts, 10 dB is 20 dB, $1000 challenge, chimp is top antenna designer, closed Open house, talking to themselves, etc. They report getting death threats and are promising to sue everybody. They sure make Howard Stern look look like kindergarden jock.
I am sure this will help.
With best wishes

We have to, Ed. They still inspect broadcast stations. Not as often as they
used to, but just as strictly. There are big fines, and the possibility of loss
of license, if we aren't found to be in compliance. RF exposure regulations
are old hat for us now. The latest big deal has been tower painting and lighting.
They've been laying some really heavy fines for not having that right.

Oh no, the dreaded indoor mag mount antenna. Death would come in a flash along with excruciating pain from the handy talkie RF field. Your only hope is to order the "Internal antenna and shield" from the local infomercial for $19.95 plus shipping and handling. (smartass mode off)

All transmitters below 50 watts on 2 meters do not even require a compliance statement. The "problem" has been so over hyped, one can put it in the same class as little green men from mars. That being said, we are required to meet the RF specs. To answer your original question, an indoor 1/4 wave antenna on a mag mount sitting on a pizza pan should work for you. If not, check into one of the stealth antenna such as the venttenna.

The FCC generally supports requiring the power company to correct problems with residential distribution lines. On HV lines, however, they generally do not. An FCC decision made in the 1970s that "corona discharge" from HV lines is a "natural phenomenon" still stands.

If the line is clean now, but develops noise in the future, you may be able to make a case. OTOH, I have seen the FCC take a position that requiring a utility to rebuild miles of HV line to protect a few hams and rural TV reception was "not in the public interest."

I agree with Tom; you may not want to take a chance, if you have housing options.

>floor speaker, but the rectification is still there and quite loud.

You may also need to filter the AC line feeding the alarm, both with RF chokes and possibly an AC line filter (Industrial Communications Engineers - see http://www.arrl.org/tis/tisfind.html or Radio Shack catalog #15-1111).

How did you make your RF chokes? One common "mistake" is to try a single clamp-on ferrite for HF; generally, an RF choke requires more inductance. Try a Palomar F-140-43 ferrite core, if the wires are small enough to get about 10 turns of wire onto it; otherwise, use an F-240-43 size core. The 43 materoal is about optimum for the upper HF range.

Sometimes you may need a similar filter on remote sensors, if they use active electronics. Also, the wiring may not be balanced well at RF, so caps across the line may be needed, *but check with the alarm manufacturer about doing this*. Some sensors may not work if they see too much capacitance.

If the speaker is located remotely from the control unit, it may be best to concentrate there. Is it an amplified speaker, or passive? An F-140-43 core, 10 turns, at the point where the speaker wire enters the control unit may help. You can also try a speaker-lead filter (Industrial Communications Engineers). Be very careful about putting caps across the speaker leads; some audio amps become unstable and overheat when confronted with a highly capactive load.

Must be a very lossy and poorly designed system on your end.

dB's are purely relative, and when I'm 20+ dB louder, what else
can one deduce? I'm running 1.2 to 1.5 KW out into an array with
about 16.5 dBd gain (including ground reflection) . The stacked
array is fed with 1" hardline, and designed with careful attention to
detail concerning any losses. So, why are you so weak???
Let's see, that is about 45 KW ERP with line losses. Not too shabby,
but certainly not 20 dB better, may 6 at most.

Compliance to the latest exposure limits is exceeded by over
a factor of 4 for distance for the worst case, 10M.

Jason, I don't know what your apartment building construction is like. If the building has a lot of steel, you may have a problem. I have an old HTX-404 which worked fairly well, but I had problems hitting one favorite repeater when I got perhaps 10 miles away. Not readable on low power, and some 'bacon frying' on high power. I purchased a flexible gain antenna perhaps 16 inches long or so with the BNC connector on it. It made a huge difference. From the location I mentioned which was perhaps 10 miles away (the vet's office), I am now full quieting into the repeater on LOW power. I have no problems 20 miles out with the HT and have used it from inside the car maybe 6 or 8 miles away with no problems (not recommended since the car attenuates the signal probably 10 dB!). At work, however, the building has a lot of steel inside and I really can't use the repeater even though it may be only 5 miles away. Walking 1 or 2 feet can bring it in or drop it out. I have to go outside to use the HT. What I am saying is that buying a gain antenna may indeed work for you - IF it isn't the building that is killing you. Do you know anyone with a gain whip for the HT that you could borrow it for a day (or an hour or so) just to try it and see if that helps?

Best of luck and 73s

Hi everyone,

here I am - living in a house which has just one possible location for a
wire antenna - the attic.

It's about 12m (40ft) long, 2m (6ft) wide.
Equipment is an automatic tuner by kenwood - at250.
One possibility for 'grounding', at 2/3 of total attic length.

My question:

How should I install a wire to get best results on as many as possible
bands.

Many thanks in advance,

Peter

Source record: 180349

Dear Cec,

There's nothing wrong with 16 feet. Or what amounts to the same thing - 80 toes. But your figure is based on an original exact dipole length of 70 feet or 350 toes which is actually a guess, hopefully in the right ball park. Under the circustances Kline can only be recommended, by some means or other, to substantially increase the overall length of his proposed antenna. To advise an increase of precisely 16 feet on each end would be incorrect if he could manage more.

But I do see what you have in mind. Another 16 feet on each end would take the antenna into the G5RV region where a tuner might be dispensed with and the system tuned up by adjusting the length of the ladderline. I hate to be such a pessimist, Cecil, but would not the feeder length be too short to be used in that manner? Especially if the shack is in a bedroom.

There's a blind operator near me who has a low dipole. It is resonant somewhere between 80 and 160m. The dipole centre passes by the shack (his bedroom) window. Feeder length is about 6 feet to the tuner. He has no worries about swr on the feedline which is open wire spaced at 5 inches.

I hear there's a continuing drout in Texas. Is it something to do with global warming ? It can't be doing your ground system much good. On the other hand a point can be reached where the soil has such a high resistivity the ground induced loss under a low dipole falls steadily.

Hi Ed, Bill (and anticipating next in thread) Chris,

the comment above:
>> Also, that dBi reference is for the gain of the antenna in situ; ie,
>over
>> ground, with any other attenuations factored (loss through buildings,
>etc.)
This may be true in any (or every) instance, but it is not the meaning
and is not the point for using dBi.
It is ammended later with:
>>The terms dBi and dBd really are
>> mathemetical constructs.
which is literally true, but the statement is not very informative.

This goes to the cry to compare like things to like things - after a
fashion.

The power of employing dBi as a method to report gain or field
strength is not in some mathematical artifice. The power is with the
basis of comparison. This goes back to Chris's complaint that he does
not see enough head to head comparisons being made with various
fractal designs being offered. Here the basis is being explicitly set
to force comparison of one fractal yagi(?) antenna against another,
conventional yagi(?) design.

This is not a particularly useful basis however, with this basis being
too constrained to be useful against any other, conventional yagi(?)
design. Now we can all appreciate that we can loosen the constraints
so that if one has a similar conventionally designed antenna, then the
reported comparisons could be inferred with regard to another antenna
"like" the one chosen for comparison to the fractal. We do this every
time we match characteristics between competing ads for antennas in
the magazines.

This reveals, however, that the "likeness" becomes a moving target and some one can once again introduce the demand that their antenna choice be made the basis for comparison against the fractal (or any design for that matter). Such clamor or demand to be basis quickly devolves into chaos or is met with an un-ending, growing list of comparisons.

So, where does this leave us, and what does it have to do with dBi?

The i of the dBi is for an isotropic radiator. A caveat to this is that such a beast is not expected to be realized as an actual antenna. And yes, this is performed through mathematical constructs. However, this last statement is not an argument, it is an observation.

The utility of dBi and specifically with the isotrope is that once a measure is made of a test antenna, it may be compared to any antenna which is similarly expressed in dBi. Thus dBi is the lingua franca, or the basis of comparison.

If you choose (or desire to have) another antenna to compare against, you simply reduce both antenna's to their dBi representations and you can judge both against the isotrope.

This method is common in metrology (calibration) and is called "transfer" and the isotrope becomes the Transfer Standard. Transfer Standards guarantee a basis for accurate measurement by being well known (thoroughly documented) and very stable. The isotrope satisfies these characteristics by being an artificial construct with a very simple criteria: an equal radiation of power in any direction. This of course means that as an efficient radiator, it is an example of the lowest gain antenna. Only an antenna with loss could have lower radiation in all directions.

This in a sense promotes the vertical which is characteristically called a radiator that is equally poor in all directions - the promotion comes by virtue of "all directions" not being technically correct (the arguer is implying a hemisphere instead of the complete sphere for one). Thus the efficient monopole will exhibit positive, equal dBi valuations in every direction normal to the axis (this is equally true with the dipole, but the perspective is distorted with the inclusion of earth).

We then move to consider polarization if we are speaking of point to point communication that is within sight. Both the vertical and horizontal dipoles will exhibit identical emission of power (in free space), but with respect to polarization, their dBi gains will be vastly different. As this agrees with experience (we call it cross polarization) the basis of comparison employing an isotrope proves its utility. Line of sight modeling is not the whole and be-all though, but further discussion will add little.

We then move to consider the environment. This is a consideration that is free of basis unless the issues are forced into the discussion. This is fine, but if such considerations are not amenable to elimination, reduction, or compensation, then they may reduce the

discussion so much as to constrain it for unique circumstances that are rarer than the isotrope. That is, not everyone has the same height tower (do you fudge for inches or feet?), not everyone has the same terrain (should you add a hill or mountain to standardize the fractal to you back yard?), and absolutely no one (except ships at sea) have the same ground.

These last issues either must be eliminated from the discussion, or accounted for AFTER the basis of comparison has been reported. In other words if antenna A exhibits 3dBi at 15 degrees over average ground, then antenna B needs to be measured on the basis of the same average ground, or reported for a different ground with a supplemental report of the effect of other grounds on that reported value. The inclusion of "real" characteristics introduces the problem of too many variables and what is called in software programming "combinatorial explosion." In other words, take all possible combinations of several variables and you may come to the requirement of reporting millions, possible billions of test results.

What price reality? Basically it is wholly unneeded. The point of Transfer Standards is that if there are differences OUTSIDE of the design, that is your problem not the comparison's. Reality is what you have to live with, period. Given two antennas provide identical results in the same "perfect" environment, then there is every likelihood that they will suffer equally in the same "real" environment. Thus if you can eliminate environment from the comparison, you are actually comparing like to like (even if there is a proxy isotrope). This is why I chose to perform my analysis of fractal antennas within the perfection of EZNEC. I couldn't possibly satisfy everyone (or even a majority) by making an arbitrary (or popular) choice of "real" ground constants.

Now having dismissed reality, it must be acknowledged that "real" characteristics may be part of the design, and that they may even be beneficial to the bottom line. The recent design of the k2 is a case in point where ground is very necessary to the design goal of optimizing take-off-angle. Ground becomes part of the antenna. You might liken it to a very lossy passive element, but useful to the single goal none-the-less. You will also note that the cost to this deadly embrace is that the antenna, overall, has no gain figure better than say -5 dBi in any direction, and often much less (which provides for a modest F/B).

The necessity of ground being included in the basis of comparison raises the odds (it toys with the probability of arguments collapsing under the weight of that mentioned combinatorial explosion), and such inclusion becomes problematic. I resolved that with an alternative design, the Flying H, which demonstrates a similar need for ground as passive element. Both designs show extreme variation in their characteristics as their elevation is changed over centimeters, not feet. Ground, for these designs, cannot be escaped nor easily

rendered into comparisons for other users who have grounds that are different (or worse, of unknown characteristic).

Thus the employment of dBi to report these characteristics is satisfying in that it provides a standard basis of comparison. Elaborations in the environment are separable and if you demand comparisons on that basis, you can amend those same reports without disturbing the assumptions made about the antennas (except for that class of ground huggers like the k2).

No. I meant the other Rain Man.

2535. from Elk Antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-20 00:00:00 UTC
From: ray gaschk <rgaschk@tpi.net>
Message-ID: <39C93515.8E69CCB6@tpi.net>
Source record: 179972

Jenni,
We (Elk Antennas) make a log periodic antenna designed for the 900 MHz band that might do the job for you. We sell it to people who have difficulty making credit card transactions with their modem.

I am unsure as to how to make the connection to your transmitter, but you could buy an antenna and try several methods to see if one would work for you. The antenna is guaranteed, if you can't make it work within 30 days, just return it an we will send your money back, but this does not include shipping charges.
If you give me your location, I could tell you how much it would cost to ship.

There is a effective radiated power limit imposed to prevent cross transmission to an adjacent cell site, and it is up to you to not exceed that limit, although it sounds like you are in a fringe area and may not exceed it.

I will include a picture of the antenna but with a extreme environment coating
which costs an extra $10, which you probably would not need. So the antenna you would get for $75.00 plus shipping would be aluminum color, not the black
that is shown in the photo.

The antenna covers the entire 900 MHz band and has an estimated gain of 5 DBd at 50 ohms and has an female SMA connector at the front end.

Best wishes from ray, w6fya for Elk Antennas

If I read Ali Babb correctly, he has a scanner he would like to use to hear the exchanges on the working frequency(s) of the taxi service(s) in Rome. He asks anyone who knows the frequency(s) to post them or to send them to him.

Best regards, Richard Harrison, KB5WZI

dBd isn't as universally recognized as dBi. A number of people have argued long and loud on this newsgroup that dBd means "dB relative to a dipole at some height over ground" rather than relative to a dipole in free space. ARRL publications are among the very few which give an explicit definition; it's used in none of the standard academic or professional textbooks. So be prepared to be misunderstood when using dBd unless you carefully define it each time you use it.

In contrast, the definition of dBi is unambiguous.

Hi Tom--

>If he fails to do what he says, he will be known as a liar and a fraud...and probably be reminded of that fact by everyone. I'm sure he wouldn't choose that path, no matter how many people try to force him
down the road of "wussing out".<

You're right. I've been way too overprotective. The past few days alone, I warned of the potential for a little "ham radio fun" turning into a major Civil Rights violation against the LDS church. Then, I offered to lend out a $900 digital Bird power meter to resolve a power output question with finality instead of calculation. Now I'm trying to prevent a major financial calamity that would devistate a family.

Like the boy scout who helped the little old lady across the street who really didn't want to go, I'm being overzealous and controlling. I'll stop before some fool accuses me of trying to be too damn helpful.

Alex,
Go to any search engine and look for W4RNL , Cebic's site. He has more info than you will care to read and it is all factual, well worth your time. He compares many antenna designs and techniques, with little personal shading, he lets you draw your own conclusions. Great guy and site, I'm sure you will find something to help.

Good luck to you, I love your city, really enjoyed a holiday there.
Best wishes from ray, w6fya

Salt marsh.

Would waves have negative impact on the
>reflective properties of the salt water?

Yes. Your 'mirror' has time-varying distortions > 1/8 wave in amplitude.

Would salt marsh have perhaps more
>salt concentration and be better?

No. A bona fide salt marsh is salt water. If you are referring to brackish estuaries the difference will be minor.

Any BC experiences or studies?

Fractenna is not a person.

I don't agree with Phil's word choice, but your comments are not worthy of this NG IMHO.

I know no one who has a fractal antenna who will now come on this NG. They have, rightly so, left it to me.

They just don't want the bullcrap from a few malcontents.

Don't blame'em.

Hi Jim,

Tweed or twill, Hmm? If the suit and pants are tailored with a cross
bias, they will drape better.

Let's not forget that the bobbin needs thread too. This is also on
topic because the bobbin can be said to be an (en)closed thread.

I won't even get into the software topic of writing "thread-safe"
methods. Hmm, there is consideration of thread starvation tho'....

You can't close an unmoderated thread, but here is how Chip was shut
down on another forum...........

Date sent: Thu, 01 Apr 1999 17:43:34 -0500
To: antennas@qth.net
From: Larry Wilson <lwilson@cyberportal.net>
Subject: [Antennas] MODERATOR's NOTE
Send reply to: Larry Wilson <lwilson@cyberportal.net>

First, let me apologize for the recent outbursts on the list.

When I arrived home and saw an unusually large number of message in my

[antennas] box, I feared the worst. I took immediate action:

1) The address Fractenna@aol.com has been permanently removed from
this
list.

2) The list is once again on full moderation until the fire storm
subsides.

This is the third time I have had to take steps to protect the
integrity
of this list, and each time the above address was at the center of the

problem. I have been more than lenient. Certainly "three strikes and
you're out" is reasonable. Even so, had this been a first offence this

person's actions would have resulted in immediate dismissal.

Posting of private messages to the list accompanied by personal
attacks
will not be tolerated. This is a breech of any accepted standard of
conduct for email list usage! Personal attacks and name calling are
equally out of place.>>>

Fractenna is closed.

No. This thread is, "This thread is closed" You were also incorrect
about the other thread that you insisted was called closed. It was
obviously called, "N1IR OPEN HOUSE"

There you go. This thread is ,"closed".

2561. Tuner vs Balun+choke

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-20 00:00:00 UTC
From: Bill Ogden <wogden@attglobal.net>
Message-ID: <39c957c6_3@news1.prserv.net>
Source record: 179998

As I get older I get more confused, it seems.

I want to feed a loop cut for 20 meters, and use it on 40-10. The top of the loop can be opened at times to change the take-off angle. This antenna will have a wide range of impedances on various bands. I planned to feed it with ladder line and a tuner. HOWEVER, I see a lot of discussion about using coax + 4:1 (or 9:1) balun + choke "washers" for feeding a wide range of antennas.

Do these two methods (tuner and open line VS coax + balun+choke+no tuner) really compete with each other? A viable solution without a tuner would certainly be attractive, since that is one less thing to adjust. Also coax is easier to install than ladder line.

I am using a fairly modern solid-state rig (TenTec) that needs to see something close to 50 ohms.

I would really appreciate a short, high-level tutorial from someone like Roy, who explains things very clearly and correctly.

Bill Ogden, W2WO

2564. Re: Best salty ground?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-20 00:00:00 UTC
From: "Peter O. Brackett" <ab4bc@ix.netcom.com>
Message-ID: <8qbn80fru1@nntp9.atl.mindspring.net>
Source record: 180001

Yuri:

I have observed at least two AM BC stations and one HF short wave station that seem to fit your bill.

Salt Water MF BC:

One is WQAM in Miami, FL which used to have their antennas situated out by "Stiltsville" just South of Key Biscayne on the reef. The last time I sailed a boat out to those antennas, from the Dinner Key marina in South Miami was before hurricane Andrew went through and so they may not be there any more. But they were definitely over pure Atlantic ocean salt water. I know that the eye of Andrew passed almost directly over that site and I have never sailed Biscayne Bay since then and so don't know the current state of the towers.

Salt Marsh MF BC:

Then for the salt marsh, there is KPO in San Francisco Bay. The KPO AM BC transmitter towers sit directly on the salt marsh on the Eastern end of the Dumbarton Bridge at the very South end of San Francisco Bay. That SF Bay salt marsh is actually used by some "salt companies" to cultivate, harvest and sell sea salt. When you drive across the bridge you are only about a hundred yards from the towers.

Perhaps you could call or write to the Chief Engineers of those two AM BC stations for some inputs.

I have been up close to both transmitter sites looking for traces of "radials" but I could not see any. That does not mean there are not any radials just that I couldn't see them.

Salt Marsh SW BC:

Yuri, you should know about this one.

It is the International SW broadcast transmitter for Radio Canada [aka CBC] located on the Tantramar Marshes on the ismuth leading into the main part of Nova Scotia. Perhaps you could write or contact the chief engineer at that transmitter site for some information on HF antenna performance over salt marshes.

Ed:

CONGRATULATIONS.

Once you get threatened with legal action from the Fractenna screen name, you then qualify for a Freaktor to be presented at the next annual award ceremony.

The ceremony happens right after the Wouf Hong ceremony and is chaired by IR1N an amateur who claims to be from Italy but who speaks with a Boston accent.

The Freaktor is sort of like the Oscar or Emmy, except rather than a figurine, it vaguely resembles a gold plated Koch.

Once you have the Freaktor in your possesion, why then DXCC honor roll first place pales in comparison.

After you are awarded the Freaktor by the NG, you then can qualify to compete for the All Thread Usenet Freaktor.

To do that you have to be threatened with legal action from the Fractenna screen name on at least 10 different NG threads.

BTW... the all time champion is Tom W8JI, he has 5 endorsements on his Freaktor!

Soon Ed you too will be among the honorable Freaktor holders.

Best,

Peter K1PO

2568. Re: Comments: Double Bazooka Dipoles

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-20 00:00:00 UTC
From: Walter Maxwell <w2du@journey.com>
Message-ID: <p8cy5.819$mC.37499@monger.newsread.com>
Source record: 180005

My analysis of the double bazooka antenna appears in Chapter 18 of Reflections, which shows mathematically that the stubs contribute zilch to the bandwidth with respect to reducing the off-resonance reactance, but instead the bandwidth reduction is due entirely to the resistive losses in the coax. Its performance is similar to that of placing a dummy load in shunt with the terminals, or similar to the TF2D (or is it T2FD?), the wide band folded dipole with a 600-ohm resistor in the side opposite the feed terminals.

Those who believe the bandwidth improvement is great are apparently unaware that the bandwidth improvement result only from power loss due to loss in resistance. The results are truly disappointing.

It's actually funny, but there's enough doublespeak to prevent
prosecution (I think). They say that the products "will not affect
reception quality" - that means to me that it won't help it or hurt
it... Anyway, the little "scrambler" thingie appears to be a Faraday
screen that goes over the earpiece hole that's supposed to act like the
screen on the door of a microwave oven. IF the phone case were
shielded, and IF the screen were grounded, then it might actually make
SOME(if nearly unmeasurable) difference in RF bioabsorption. Lots of
IFs... I think these are products designed to be SOLD rather than
USED...

Isn't the point of a Beverage antenna to produce a low-noise (high S/N ratio) signal of around 10 db or less actual amplitude than a comparable longwire antenna?

Simplistic answer:

1. A lot of math; there is no "simple" formula.

2. Model them with something like EZNEC (http://www.eznec.com) which does
the math for you.

I recommend #2.

Since making a false accusation of felonies ("harassment and death threat")
would make a false accuser liable for civil damages, and if the accuser
identified himself as acting as an officer of a company, the company would
also be liable for civil damages if the accusations were false, there
exists the possibility of an ownership change in a certain antenna company.

Which leads one to wonder:

1. What would Tom's major product line be in his new company?
2. Would "Phil" still hava a job?

Howard Stern is broadcast on some radio stations in Canada. You will
NOT hear Howard Stern's broadcast over the internet.

As for web sites, here is what I know about Howard Stern's web sites.

http://www.koam.com

This is NOT an official Howard Stern web site, but it is the most
popular.

http://www.howardstern.com

This IS the site owned by Howard Stern, but he does not wish to put up
a web site, but rather keeps anyone else from using it. He has a very
simple page of info there not meant to be an official web site.

2575. Re: Building helical antenna to span 470 to 850MHz (UHF TV)

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-20 00:00:00 UTC
From: Spencer Webb <webb@alum.mit.edu>
Message-ID: <Kb6y5.1012$2l.20315@news.shore.net>
Source record: 180122

Forget making the helix conical. Pick the geometric mean of your frequency edges, 632MHz, and build your helical to those dimensions. It will work, and will perform well over that broad bandwidth. Forget impedance matching, you'll have a 2:1 SWR with 75-ohm cable (about 140-ohm impedance when peripherally fed).

Helicals on a conical surface provide interesting tradeoffs in gain and bandwidth, but it is a complex issue. Standard helicals perform well over a 2:1 range, but not too much more.

Build it. I think you will be delightfully surprised.

A long shot on this but thought I'd try.
We had a big blow last week and my 2 meter antenna
shed its tip. The base mount cracked off and I need
to replace it.
Any chance there is a partial available in your junk
pile? All I need is the aluminum mount with three bolts
that attaches to the mast with the short rod that is mounted
to it.
I don't believe AWA is in business anymore. Might be that
some other firm bought that line.
Help in Iowa ,Tnx for reading.
Mike

Hi Jim--

You're right. Should it ever be demonstrated that someone's motive for making a "death threat" claim were part of a pattern of predacious retaliatory behavior, and if that a pattern included the issuance of similar false claims against others in the past where no tangible threat existed, the punitive damages could be huge!

> Thanks Dan WA6PXO

Dan,
You can add elements to the A3S, but extend the boom when you
do. You will get some 'gain' by adding elements, but not 3db per
element, by any means. I'm not sure it would be worth the effort.
After a point, the boom extension gets to be a real 'pain' to do
so that it's mechanically sound.

From: 'Doc <w5lz@oio.net>
Message-ID: <39C90832.77A2398@oio.net>
Source record: 180137

RadioFreq0,
The AT-50 is more of a 'line flattener' than a full blown,
or wide range tuner. It will certainly work mobile, but don't
expect the frequency agility compared to a screwdriver. It
won't make a 'Hamstick' into an all band antenna.
There are a couple of modifications for the AT-50 that you
might as well do to start with. Any of the 'Mods' sections
of QRZ/Kenwood/(?) internet sites should have them. These
mods deal with compatibility problems , and will save you from
changing fuses a lot.
Mounting the AT-50 in the trunk, or as close to the antenna
as possible, is 'better' than having it at the radio end of
the feed line.
I've had two AT-50's, and ended up taking them out of line
both times (didn't know about the mods then). I haven't put
it back in-line yet, just too lazy, and got used to doing it
differently.
Good luck...

> Before you buy.

Lee,
A good ground ~always~ helps an antenna, no matter what kind it
is.
Rather than a different length radial(s) for each band, use as many as
you can for the lowest band of use. You'll know when you should quit
adding radials. Back hurts, you become 'sick' of the whole idea, you
wonder why you ever thought you wanted a vertical, etc. At this
point,
add two more...
'Doc
PS - Best way to measure radials is by the mile.

2594. Re: Crazy? Receiving antenna experiment

Source record: 180141

Tom, W8JI wrote:
"---your book may say otherwise but that isn`t how it works."

In the days before TV there was a time when few radios had built-in antennas. Most broadcast listeners had a connection to ground and a more or less horizontal wire to receive transmissions of about 545 meters to 176 meters. These are wavelengths of about 1788 feet to 577 feet.

Most receiving antennas were only 50 or 100 feet long and only 20 or 30 feet above ground, because it worked and it was easy to do. Even at the high frequency end of the band, the height and length of the aerial wire was low and short in terms of the wavelength.

An antenna 20 feet off the ground receiving a 1 MHz, (wavelength of 300 meters or 984 ft.), signal is plenty near enough to the ground to see wave tilt.

An aerial only 75 feet long won`t have any net gain to speak of in the broadcast band, either. But, such wires worked reasonably well, and better in some directions than in other directions and thus they gave gain in the favored directions. The problem is that the ground, due to its closeness wipes out any gain. In non-favored directions, the ground not only wipes out the gain, but the loss also reduces some of the interference or whatever is in the non-favored directions.

A 75-foot wire is not a Beverage antenna at broadcast frequencies. You look for about 2 wavelengths. Even a "short Beverage" is usually 300 to 600 feet long. But if you had a half-mile of wire strung out and it were not at the bottom of a ditch or other ill-concieved site, you would have real gain. Some or all this gain could be wiped out by loss, but it isn`t necessarily so.

Best regards, Richard Harrison, KB5WZI

I wonder if there are any practical experiences pointing to the best ground for HF for use with vertically polarized arrays.
The question is what is better, situating the antennas on the beach next to the ocean, or is the salt marsh better. Would waves have negative impact on the reflective properties of the salt water? Would salt marsh have perhaps more salt concentration and be better? Any BC experiences or studies?

Can you demonstrate or prove why only certain, particular (fractal)
shapes would have the performance characteristics of your antenna?

Tom, W8JI wrote:
"Just like the 1/4 wl long folded dipole TV antennas? If it`s in a book, it must be right...eh?"

Not because it is in a book is it right. It is in a book because it is right.

A 1/2 wavelength of wire is resonant because its reactances add, at that length, to zero. A 1/2 wavelength of wire formed either into a loop or !/4 wavelength folded dipole may be resonant. Both have a high drivepoint resistance because their drivepoint terminals are 1/4 wavelength away from a short circuit.

The drivepoint resistance of the loop is typically 10,000 ohms or more. The drivepoint resistance of the 1/4 wavelength folded dipole is typically 4000 or 5000 ohms.

In either the loop or the dipole there is no reactance to limit current. The high antenna resistance must be matched for maximum power transfer, but it`s feasible.

Both the loop and folded dipole have gain over the isotropic radiator. In fact, even the itsy-bitsy elementary doublet has gain due to its directivity. Terman on page 871 of his E&RE book says the power gain (not db) over an isotropic is 1.5 for the elementary dipole. He also gives the gain of a 1/2 wave resonant wire as 1.64. So if you get current into the 1/4 wave dipole, there`s hardly a dime`s worth of difference between its performance and that of a 1/2 wave dipole.

Best regards, Richard Harrison, KB5WZI

While I dislike my name being brought up, I don't think we should do anything that intimidates Chip and prevents him from doing what he has to do to preserve his reputation.

If he has to do what he claims he has to do to preserve his reputation, than I'll just have to suffer with the outcome.

If he fails to do what he says, he will be known as a liar and a fraud...and probably be reminded of that fact by everyone. I'm sure he wouldn't choose that path, no matter how many people try to force him down the road of "wussing out".

After all, he has a well-established reputation to uphold.

Hi Yuri,

I'd use regular old phil dirt mixed with assalt.

Run it through the chipper, and spread it out in many small well mixed
chunks.

Seriously, I'd think either one would be excellent! I don't know which
would be better.

That is a good reason for my use of the word "appears," NC (do you wish me to call you by NC when you sign NC and Chip when you sign Chip?). Unfortunately, I have not been able to find any information that really explains how a fractal design is different than linear loading, so until there is some, I am afraid that all most people can have is speculation.

> Please do not try to engage me in conversation. I do not believe that you

I am sorry, NC, but when you post publically, the public is quite free to post in response. If you choose not to respond to me, that is your choice.

> A linear loaded antenn cannot do what this antenna does.,

> Period.

Well, I think that the "period" is where the difficulty is found, NC. Most scientists who make statements support those statements with facts rather than periods.

> >Perhaps you should consider posting the model,

> No.

Your choice, but in witholding information that could support those things you say about the antenna, you cannot really take issue with those who do not fully understand the reasons for your statements.

> The last thing I am going to do is post a 200 wire model as a file on this
NG.

You could put it up as a link on your Web page. It really would help replace some of the contention over this issue with understanding.

The reason that antennas are compared to dipoles in free space (dBd) or an isotropic source (dBi) is that this allows the most meaningful comparison of antennas. If you know the gain in dBi or dBd of the antenna you want to compare the fractal to, you can easily subtract the difference and obtain the necessary comparision. IMHO, Fractal is quite correct in selecting a universally recognized standard for antenna gain.

True. If loss is insignificant (or neglected), ANY antenna has gain in some direction(s) relative to an isotropic radiator. The isotropic radiator has the lowest possible gain of any 100% efficient antenna.

As you point out, the gain of an infinitesimally short dipole is less than 0.5 dB less than for a half wave dipole, if loss is ignored. In practice, loss can't be ignored for a very short dipole due to the heavy current involved. In addition, matching system loss becomes more and more significant as the dipole gets shorter. It's not hard to get a signal from a quarter wavelength dipole to be within a couple of dB of the signal from a half wavelength one. But it gets much tougher as you make it shorter because of the unavoidable realities of loss.

One other consideration when using a short dipole is bandwidth. The bandwidth will be much narrower than for a full sized dipole, unless the system is exceptionally lossy. So unless adjustable matching is used, practical operation will be limited to a narrow frequency range.

But what if he references it to a real dipole near the ground? Which already has 5+ dbd? I think that this is the issue which was trampled here in excretia several months ago.

I have gotten the impression that comparisons were made and reported elsewhere between near-ground-mounted antennas but reported in terms of dbd and dbi without making it clear that the ground-enhanced gain had been accounted for.

Several have made the point that near-ground dipole comparisons are of limited validity since "near- ground" and other near-field surroundings properties are not constant.

Ed, how about some Socratic wisdom in this area?

I am dissapointed, the most important question in the RF field and you dunno?
It doesn't help at all.

I wonder if way to test or measure it would be to try to see how much signal is
received on particular frequency in certain depth in the ocean or in the salty
mud. I speculate that less signal would indicate better, reflective ground
surface for them verticales?
I am hoping that someone has done the survey while looking for BC sites.
I am willing to travel to the best possible ground.

Tnx, Yuri

sideband <sideband@cac.net> wrote:

> Dipoles vary, as do all antennas. A dipole tested at one site will
> perform slightly differently at another. Two different dipoles at the
> same site will perform slightly differently than each other.

Yes, to a relatively minor degree, but yes. This is why the term dBd has a half-wave dipole in free space as the reference antenna. If a dipole tested at one site will perform slightly differently than another, then the same thing could be said for the Yago or other reference antenna you are asking him to compare his antenna to. If the testing really were done on a calibrated antenna range, most of those site differences would be calibrated out. On a calibrated range, one can either apply power to an antenna, measure the field or power density at a particular point, and calculate the gain from that measurement (in that azimuth/elevation direction) or can A/B compare the measured power density against a reference antenna on the site (that presumably has very well documented performance). That is my general understanding of the subject; I am sure there are some on this NG who can add a lot to that generalization.

> It is the convention, yes, and it gives a certain set of data, yes.
> And that data is used to compare antennas, yes. But, as stated before,
> dipoles vary. Conditions at testing locations vary. Ground varies.

Which is why ONLY testing done at a calibrated antenna range can be seen as reasonably accurate. Modeling can be reasonably accurate too, to the extent that the model matches the conditions under which the antenna will be installed, or at least matches some reasonably agreed upon standard set of conditions. For the basis of comparing antennas, average ground conditions are usually acceptable as a reasonable basis for the model. The patterns that Chip has posted appear to have been modeled under those conditions, so I accept the results as a good first approximation of the performance of his antennas.

> So what exactly are you afraid of? This comparison between your Yagi,
> and any other Yagi of the same frequency range will only serve to show
> the merits of your rediced form factor design. I don't see what the
> big deal is here.

Then make the comparison; take the modeled gain figures of any Yagi, convert them to dBd and do the subtraction.

> Or is it that you don't want the world to know that in your FQY all
> they're getting is something that's only slightly better than a
> dipole, and directional?

If 3 dBd is "slightly better" than a dipole to you, then that is what you can infer from the data published on his page. But don't discount the value of "directional." Although that 3 dB won't make much difference on transmit with strong signals, that F/B can make quite a difference on receive (I would be curious to know how much that F/B varies across the 10 M band, though -- at least across the CW/digital/voice/FAX portion of the band; that is why I was hoping to get a NEC model. If any of you have typed it in from the dimensional data on the page, please email it to me; I just don't have time to input the data.) Not only will you not hear the signals off the sides and back, more important, you won't hear noise (local or atmospheric) off the sides and back, giving an improvement on receive > 3 dB in the resultant S/N. On receive, I would take 0 dBd gain and 25 dB F/B over a dipole any day.

And, in reality, the gain of 3 dBd for that 10M quad looks to be reasonable, and it is presented in a way that is relatively straigthforward.

I really don't see what the beef is wrt the antenna's performance claims.

Of course, if one is trying to do some sort of measurement of the gain of an antenna, ideally, the building wouldn't be a factor at all. :-) If a real world gain, if the building acts to add gain, I would figure it in; if it subtracts, I would figure that in, too. Otherwise, how would one differentiate between a gain change that was as a result of propagation loss through a building and one that is the result of the addition of more "parasitic elements" due to the building, which could just as easily detune the antenna and change the current and phase relationships and decrease the gain (and degrade the pattern) through that mechanism.

I picked a few nits, so you are welcome to do so. I usually round to the nearest 0.1 dB when I give results from EZNEC. Even then, I doubt that there is a full 0.1 dB of precision between the model and reality.

No its not!
As anyone can see!
Is anybody alive who survived Fractal Closed Open House?
Please feel free to enlighten this NG, your opinion, remarks, experiences, what was learned, etc.
This is thread, not a threat! And it is open, open, open!

2620. Re: N1IR OPEN HOUSE The continuing saga of the thread that chip has deemed closed but nobody else seems to give a rats ass what he wants and continues to post here anyway.

If the thread was closed you wouldn't keep posting to it now would you? Besides, you already had your chance at answering the question and got it wrong. Now step aside little boy and let somebody else have a crack at it.

Was it, "I'm a good driver. Yeah. I'm a really good driver. I like to drive. I'm a good driver." ?

To Readers:

I have just sent a letter of complaint to Mr. Rauch's local police for his harassment and death threat. I will also be contacting the FBI once I have had a response from them.

If I need to go to Georgia to press charges I will do so.

Now: on measurements.

The FQY measurements on the ham page were done at WK1O's QTH. He has about an acre of clear, flat, marshy terrain.

See:

http://www.fractenna.com/ham/hampage1.html

>>
>>73,
>>Ed Hare, W1RFI
>>

Speaking of antenna efficiency, which was discussed earlier in the
previous thread, I see that SM3IEV's yagi analysis software has been
released into the public domain. It calculates antenna efficiency,
and also G/T for VHF/UHF yagis. It also has the freespace dimensions
for a number of good yagis for VHF and above.

It can be found at:

NC:

As I stated before, You haven't been reading all of what I've written.
Your sentance concerning the ERSATZ and WHANGboomer proves that.

I have been asking questions; you have yet to answer them.

Compare your Yagi, with any Yagi of your choice, on a calibrated
antenna farm, at a respectable testing facility, and let's see some
data. Interpolated comparisons could be inaccurate, so let's see the
real thing.

I test antennas almost everyday. Fractal Antenna Systems, Inc. has a reduced reflection compact range.

I have reported the MI2 results here, on this NG, several times. The measurements have been published--several times.

I have reported them elsewhere on other internet forums--several times.

Your ignorance is not someone else's failure.

Nope.

I will never, ever, do that.

The dipole is the benchmark. It is the convention.

If, as a CB'er, you require a different 'standard', then I suggest that at least some CB'ers need a better education in antennas.

I can suggest books if you have a serious interest.

Again, NC, you get it wrong.

I am not a CB'er. I'm a CB operator. The only thing holding me back from getting my license is morse code, and that due to a form of dyslexia that apparently the FCC doesn't recognise, but the medical community does. This was a feeble attempt at an insult, Herr Doctor, and should be below someone who has purportedly had a higher education.

Dipoles vary, as do all antennas. A dipole tested at one site will perform slightly differently at another. Two different dipoles at the same site will perform slightly differently than each other.

It is the convention, yes, and it gives a certain set of data, yes. And that data is used to compare antennas, yes. But, as stated before, dipoles vary. Conditions at testing locations vary. Ground varies.

So what exactly are you afraid of? This comparison between your Yagi, and any other Yagi of the same frequency range will only serve to show the merits of your rediced form factor design. I don't see what the big deal is here.

Or is it that you don't want the world to know that in your FQY all they're getting is something that's only slightly better than a dipole, and directional?

Oh, and while you go about spouting your involvement in radio astronomy, I'll have you know I'm involved in the SETI project as well. You don't have the market cornered on this one either.

-SSB

On or about 20 Sep 2000 13:13:25 GMT, fractenna@aol.com (Fractenna), using the forum rec.radio.amateur.antenna did say:

:>Compare your Yagi, with any Yagi of your choice, on a calibrated
:>antenna farm, at a respectable testing facility, and let's see some
:>data. Interpolated comparisons could be inaccurate, so let's see the
:>real thing.
:
:Nope.
:
:I will never, ever, do that.
:
:The dipole is the benchmark. It is the convention.
:
:If, as a CB'er, you require a different 'standard', then I suggest that at

:least some CB'ers need a better education in antennas.
:
:I can suggest books if you have a serious interest.
:
:NC

Why don't you enter their "disk jockey" names into a search engine?
Those are the names their web sites would be under.

Howard Stearns and Don Imus, by the way, are their real names, I
believe.

Don is on WFAN. You might do a search for that web site.

Best...

Hi

Perhaps my first message was not clear about this, I would like to learn the names of as many shock jocks as I can. In Canada we do not have shock jocks, I'd like to listen to one over the Internet.

Thanks for your help!

Stan

>the passband = interference.

Yeah, but if the spectrum is sufficiently whitened, and sufficiently dispersed, it should merge with the noise floor of the analog spectrum analyzer, and not produce more than a slight degradation of the SNR of conventional narrowband equipment, when operated at any reasonable physical separation.

(If you get close enough to the source, you will be able to see it as a hump on the spectrum analyzer, of course. That's the classic near-far problem with SS systems. But with a reasonable separation, the energy disappears into the noise floor for any receiving system except one using the same spreading code. That can despread the signal and recover enough energy to produce a positive SNR.)

But the problem here is that some of the stuff being installed doesn't have a sufficiently whitened spectrum and/or has insufficient dispersal. It has pronounced spectral lines with sufficient energy to bother analog systems such as the broadcast remote pickup receiver I mentioned. The fact that it puts a buzz on a 443 MHz FM receiver when it is operating in the 2.4 GHz band is another indication that strong spectral lines are present (and mixing somewhere on site to produce products that get through the repeater receiver's filters.)

SS technique isn't the problem, poorly designed SS equipment is the problem.

Gentlemen: Has anyone tried adding additional elements to a standard commercial triband yagi (Cushcraft A3S) I have an old Th3jr and thought there might be an advantage to adding a couple of directors to the A3S. The th3jr elements are light weight and would not require too much in the way of boom reinforcement. Could get 3dB or so. Any comments ? Thanks Dan WA6PXO

Someone here is Stupid. Don't want to mention any names.

Who here is Stupid enough to think the police is going to have
any interest in what was posted on an Antenna Newsgroup on
the internet.

Even so, the first action would be an investigation,
They would start by reading the post of all involved.
There conclusion would be someone is stupid,
wonder who's name would come to mind.

From: Dan Bryden <dan.bryden@boeing.com>
Message-ID: <39C8DB9F.13931028@boeing.com>
Source record: 180190

Lee, Most important for ground mounted Marconi antennas is the conductivity of the ground and that it be clear of obstructions. There is not a strict requirement for exact length of radials when mounted on the ground as there is when it is configured as a ground plane. The radials on the ground just make up for poor ground conductivity. If the ground is conductive the radials are less important. I use a full size Marconi antenna on the ground for 40 and 30 meters with just one radial of about 25 feet. The antenna works well and has a very flat swr. The more radials the merrier but practically speaking you quickly reach a point of diminishing returns. I would try it without radials first and then add some and see if the signal reports change. Good luck, Dan WA6PXO

3dB is a LOT- if you could get it. Ehrenspeck and Poehler et al have shown
that to increase a yagis gain by 3dB requires a boom length increase of
almost 2X- and this is for single band optimized yagis.

Del Shannon would be proud of you Peter.

I suspect no one was at the N1IR open house, except the people who
normally use the fractenna keyboard.

I have heard any else say they were there, have you?

I think Chip wants this thread closed so he can call the FBI. He want
to close this thread, and open the X files.

Hardly.

I have, in the past, received over 600 e-mails a week. I must separate the wheat from the chaff. I no longer answer ham fractal antenna requests, but direct them to the fractal antenna reflector.

Some, like yourself, initially appear reasonable in approach and then reveal an inappropriate core.

There are lots of other people you can talk to; I suggest you talk withh them.

Cordially, NC.

This is a typical uninformed, ham operator response.

Both model and measurement data are on that ham page. If you do not understand how to use it, then don't blame someone else.

But as you have no name anyway, what are we to suggest to you?

Stop right there. You have no idea what a fractal is, and what linear loading
is, if you say this.

Please do not try to engage me in conversation. I do not believe that you have
a sufficient knowledge base to publicly inform others on this, and based on
your previous, inappropriate behavior, you do not deserve any further
attentuion from me.

A linear loaded antenn cannot do what this antenna does.,

Period.

>Perhaps
>you should consider posting the model,
No. I have given over 780 copies of the model out since 1996.

The last thing I am going to do is post a 200 wire model as a file on this NG.

so all of us lazy people can avoid

:how to use it, then don't blame someone else.
:
:But as you have no name anyway, what are we to suggest to you?
:
:NC

Well, there's where you're wrong, Chip... I'm not a HAM operator, I'm
a CB operator. I've made no effort to conceal that fact. I am
uninformed, about alot of things, and while you continue to withold
that information which would "inform" me, I will remain so.

I've asked, repeatedly, for performance data on like antennas. You
have not been forthcoming with this information, and, therefore, are
the cause of my being uninformed. Since you caused this situation,
either quit whining about it, or remedy it.

Let's have some comparison data betwen a FQY and a standard Yagi. What
are you afraid of, here? I'm sure most understand that an antenna with
a reduced form factor will necessarily perform less well than a full
sized antenna. I'm interested in knowing HOW MUCH less.

Comparing the FQY to a dipole shows some nice numbers, for sure, and
they have meaning when deciding between the FQY and an omnidirectional
antenna. But those numbers are meaningless when comparing the FQY to a

full sized directional antenna. I'm sure one could extrapolate a rudimentary comparison by comparing the numbers from the FQY:dipole and, say, a Moonraker:dipole comparisons, but those numbers will be removed from true readings, and not show the true benefits/caveats of the FQY vs a moonraker, or some other full sized directional antenna.

What are you afraid of, Chip? That your beloved Fractenna design won't prove useful vs a full sized antenna? That's not the point of my questions. As I stated before, most operators understand that a reduced form factor antenna won't perform as well as a full sized antenna. I'm interested in how much less, if at all, the FQY would perform vs. a full sized antenna, with real data on an actual comparison.

Well? What's it going to be?

2687. Re: NEC4 Model of MI2 Fractal Loop Vs ...Who Knows ??

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-20 00:00:00 UTC
From: fractenna@aol.com
Message-ID: <20000920050447.22365.00000113@ng-fc1.aol.com>
Source record: 180234

Well Steve,

You have me thoroughly confused.

From what I have seen of the two antennas you described, here is my summary. Kindly correct me if I am wrong.

1)You are confusing directivity with gain as your models do not distinguish between directivity and gain. Gain is the directivity times the effiicency(expressed on a 0 to 1 normalized scale), then converted into dBi --for example. [NOTE: the directivity and gain of MI2 at it's lowest resonance are very similar; they are within about 1/4 dB.]

2) You mention a spiral design--which looks like you fit into a 1/8 by 1/8 wave form factor, but now is only 5 inches in size on 20M... You ascribe this antenna with a directivity that is the same as the MI2--and a higher radiation resistance;note that radiation resistance is the non-ohmic real impedance at the current max...

3) You talk about an "arbitrarily chosen" random design which you claim has basically equivalent directivity and BW to MI2.

Let me comment on the 3 points.

On (1), I do not know if your models are capable, or include, all components of ohmic loss. IMHO, you should run directivity CORRECTLY and include all components of ohmic loss Then you will actually have a directivity.

On (2), you further call this "helically wound". Now I am VERY confused. Is this a 3rd antenna?? Are you referring to a flat spiral, or is it something else? Surely you do not expect a 3-D COIL to fit into a 2-D form factor...

The flat spiral so described will have a very low radiation resistance and a very low directivity. It is very, very electrically small.

On (3),I suggest that you do, indeed, publish your random design--as any small antenna --the MI2 a prime example-- with 1.9 dBi **directivity** and high efficiency is valuable. I do, however, have grave doubts that you have such a design, based on your confusion between directivity and gain.

I would like to give you an opportunity to recant your statement that you have an "arbitrarily chosen random design". This is surely wrong. This says that one may choose any other random design and attain the same result.

Is there yet another antenna: ''a "helically wound loop"? Did I miss this? I hope you understand that this is not a 2 D form factor, and cannot meet the rules of the fractal antenna challenge.

That's right.. there's a comparison there between a dipole and the
FQY. Nothing comparing the FQY to any other directional antennae.

So where do those numbers hide? The ones comparing the FQY to a
directional antenna, I mean.

Yes; they were made in comparison to a dipole. This is the convention in antenna measurement, whenever possible. I am sorry you are not aware of that.

Perhaps you may ask such related questions to others in the group.

2696. Crushcraft AV-5 Question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-20 00:00:00 UTC
From: kc4art@hotmail.com
Message-ID: <8qa22j$503$1@nnrp1.deja.com>
Source record: 180243

I just aquired a Crushcraft AV-5. It will be ground mounted. My question is about the radials. I am going to bury them so I don't have to take them up each time I mow. I am going to just lift up the sod and bury them about 3 inches or so. What I need to know is will it work to put each radial for the different bands in the same trench, or do I need to space them out from each other so they are not touching? I am thinking that I would need to keep them separated, but I'm not sure. Also, would radials for just 80m, 20m, and 10m work fine, or do I need to run ones for 40m and 15m also? I know idealy I would want a set for each band, but how much better would that be over what I would get for using the radials for just those 3 bands? Most of my operating is on 20m and 10m anyway. Thanks in advance for all your help.

>On (1), I do not know if your models are capable, or include, all components
>of ohmic loss. IMHO, you should run directivity CORRECTLY and include
>all components of ohmic loss Then you will actually have a directivity.

Steve, this could certainly answer the questions about the last tenth of a dB or so. Do you have EZNEC? If not, send the model to w1rfi@arrl.org and I will run it on EZNEC to answer the question Chip is raising.

>I would like to give you an opportunity to recant your statement that you
>have an "arbitrarily chosen random design". This is surely wrong.
>This says that one may choose any other random design and attain the
>same result.

I think I can see the confusion; a truly "random" design could be resonant at any random frequency or frequencies, complicating this discussion immensely. Perhaps it could be more accurate to describe his antenna simply as a random design that meets the resonance criteria; certainly there are a lot of easily discovered possible designs that are sufficiently random.

I was aware it was a convention to compare antennas to a dipole. I was
asking a different question, for different data.

:Perhaps you may ask such related questions to others in the group.
:
:NC
:

Hrm... apparently you haven't been reading what I've been writing, and
your posts in response to what I've written are concocted specifically
to cause me distress. Not that they are effective; they are not.

You wonder why it is a few here on this newsgroup are critical of you?
Perhaps this is the reason why. It seems that you hold yourself above
those in this newsgroup, and therefore, refuse to answer specific
questions. Or perhaps it is because you don't have the answers
yourself?

Might I suggest you hire a publicity agent, NC? You're not going to
sell many antennas without providing some modicum of information about
them. Perhaps a publicity agent or a PR person might be more
forthcoming with data about the antennae you plan to market, inticing
more people to purchase, or at least buy in to the idea they may be
benificial.

Just a suggestion.

Helps, keep the spiders from being electrocuted!

Seriously, it doesn't really matter, the "ground" is not needed for the tuner to work properly. Your whole system is actually designed to be and should be physically symmetric or balanced with respect to ground and thus does not need to work "against" ground.

In fact if the "ground" connected to the "rotor" is not done properly, which is really quite a difficult practical matter, it will tend to upset your setup.

I would just run without it, but take care that you don't get an rf burn or shock while adjusting the capacitor, use an insulated shaft and keep your hand and fingers well away from the body of the capacitor as you tune the cap.

Any of you using an AT50 with a TS50 in a mobile setup? How are you configuring it and with what type antenna?
Can I put my AT50 in the trunk? Is it a waist to use a 20 mtr hamstick for multiband ops?
Aside from using a screwdriver, what can I do with the AT50 in my mobile? Or is it really for base/portable ops?
tnx,
Jeff

2705. Re: Stupid question

Newsgroup: rec.radio.amateur.antenna

From: Adam <jabbaSPAMJAM@w3.to>
Message-ID: <39c89b0d@grissom>
Source record: 180252

I use a loop antenna here that has about 90 metres of wire in it, and a 9m length of 300 ohm tv ladder line. It is resonant on 160 and 80 without a tuner, if I shorten it by around 3m with alligator clips it will work on 15m and do 10 through a tuner (All checked throught the MFJ antenna analyser). So I don't see why it couldn't work, but I thought 1/4 verticals were in the order of 35 ohms anyway...

Actually, if Chip's intent really was to end the thread, the muliple posts he did are more than likely to have the opposite effect, from what I have seen of the "style" some of the other rraa denizens use to discourse with Chip. I fear that some will see this as the tossing of the gauntlet. It wouldn't be at all surprising to see some start changing the names of other threads, for example.

Frankly, I had hoped that rec.radio.amateur.antenna would have less of this sort of goings on than rec.radio.amateur.policy, but apparently most newsgroups and discussion boards end up at this point sooner rather than later.

My comments were not directed to you sir; furthermore I have asked you to stop
communicating with me.

My statement was clear. IF such a random loop exists, it, by definition of
'arbitrary', cannot be arbitrary in how it was chosen.
If this were so, then it would be just as likely that its attribute would be
shared by many, if not all, others.

Just an abswer:

It is the convention to compare ANY and ALL antenna being so tested with a
dipole.

Do you understand that if you compare a ERSATZ yagi to a dipole and a YUMYUM
whngboomer to a dipole, that the ERSATZ and the WHANGboomer are thus
comparable?

As I said, you need to ask questions rather than assume incorrect knowldge.

I can think of a number of possiblities. He may be having a newsreader problem, although I have never heard of the AOL newsreader repeatedly re-posting the same response. He may have realized that the points that everyone raised are really correct and he wishes to cede them and move on. He may really be trying to end this particular discussion, however I fear that his approach will have just the opposite effect. Perhaps if he had kindly pointed out that the thread has mutated a bit and that it is time for a subject change, the rest of us would probably agree that doing so is appropriate usenet netiquette and do so. Repeatedly declaring threads "closed" on an unmoderated newsgroup is not considered good netiquette, in most circles.

Either way, it is moot; we are free to continue to discuss the points being raised, with or without anyone's consent. I will continue to partipate to the extent that the discourse remains civil.

Amen.

To the tune of many many dB. If ground losses didn't "eat away at the
gain" a great amount, the Beverage wouldn't work at all. It is the
large amount of loss in the earth that allows the Beverage to work. At
a height of .05 WL or less the wire would become a virtual
transmission line over perfect ground, with the vertical ends the
major source of radiation.

We certainly can't compare a long wire a large fraction of a
wavelength above earth to a Beverage .05 WL or less above earth!

Even at a height 1/3 of its length, longwires experience so much
current loss along their length due to coupling to lossy earth below
the antenna and losses in the wire that gain reaches values lossless
theory predicts. Actual measurements show longwires limit gain at a
length between 3.3 and 4 wavelengths when installed at a height 1/3 of
their length above earth.

>Some Beverage antennas will retain some gain when close to the ground.
>Some will not. It is simply a matter of whether the difference between
>the antenna gain and the ground loss is a positive number.

It's well established by hundreds of users Beverages suffer huge
losses compared to antennas like properly installed verticals.

Modeling programs agree totally with the results people see.

Just like the TV antenna book about 1/4 wl folded dipoles making good
antennas, the War Departmnent book is wrong

Careful sideband, Chip uses the worse comparison standards imaginable.

If you read his tests carefully, you'll see they are all but
meaningless.

First, he is on a large rock ledge overlooking a major highway. From
his house, you can see Boston and the Atlantic ocean.

There are fences behind him, and large structures. His site is
cluttered except for a clear shot across to Europe and Africa.

It would be virtually impossible to tell how anything works in an
environment like that, especially with his habitually sloppy
measurement methods.

2720. Re: Crushcraft AV-5 Question

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-20 00:00:00 UTC
From: Mogens <petsen@lazy.dk>
Message-ID: <8qaa8f$k8a$1@news.inet.tele.dk>
Source record: 180267

Basically your radials are detuned by the earth, so talking about resonant radials is not the idea. And therefore the question of having different radials in the same trench make no sense. If the antenna was in the air the answer would properly be to separate them.

Radials for a ground mounted vertical are : Many and as long as possible.
The ultimative solution is 120 radials with the length of 1/4 wavelength, but "smaller" will also work.
This is done to overcome the (typical) bad conductivity of the soil around the antenna, and thereby minimise the ground loss. Gives a better efficiency instead of loosing your power.

If you were going to have say only 4 radials on a ground mount vertical you will experience something like an expensive dummy load. :-)

Mogens (oz1akn)

Tom:

That's the point. I'm wondering if he's ever had his antennas tested
at a lab, a calibrated farm, or anything of the sort. I've asked
before, and gotten no answers, so I figured maybe this was a way to
get that data.

Maybe it's naieve of me to think that fractenna will be forthcoming
with data on his "new exciting technology", blow out the hype, and get
down and dirty with some real numbers. ::shrug::

Ed:

I apoloise, first of all, for clipping all of your post. It was too long, in my estimation, to keep reposting, and adding my comments.

The reason I suggested comparing a Moonraker 4 to a FQY is this: I'd like to see what the comparison is between yagi and yagi, dipole and dipole, and vertical and vertical. Comparing the gain of a yagi in a particular direction against an omnidirectional dipole (which, by the definition of most, transmits equally poorly in all directions) doesn't seem fair. The field strength of the yagi in the direction its pointed is going to be stronger than an omnidirectional antenna.

This is what I meant by apples to apples, and oranges to oranges. I was interested in the losses, if any, incurred by using a Fractal design on the same band/frequency as the same type of non-fractal antenna. Thus the comparison between yagi's, dipoles, and verticals.

I apologise if my post was misleading in this respect. I hope this clears it up.

Dear W1RFI@arrl.net--whoever that is at the moment;

When someone calls 666-1541 they have access to many, many people.

When someone CALLS from 66-1541 it could one one of many,many people.

Same with a screenname.

If your curiosity is merely idle, then why :1) burden me with it; 2) ask a question which I have answered at least 4 previous times, and is this readily accessible on archives; 3) feel compelled to ask it in a public and global medium?

Who cares? Why should they?

Source record: 180353

In a perfectly balanced system - the tuner, feedline, antenna, the rest of the world, etc. - the rotor "assumes" a zero potential. Actually connecting it to whatever you consider to be "ground" makes that true within that limited universe.

To the extent that all that other stuff really is balanced or nearly so, then grounding the rotor would probably produce the effect you experienced: little or none.

Goody dooby? :-)

>Go ahead and do everyone a favor and tell them what is wrong.

The performance of the fractal quad appears to be just about what I would expect from a 2-element gain antenna that size. The "fractal" approach appears to do a nice job of relatively low-loss linear loading of the elements. Perhaps you should consider posting the model, so all of us lazy people can avoid typing it in. The model would not offer any info that is different than that which is in the dimension table and perhaps some will feel more comfortable with the results you cite if they can play with it a bit themselves. I see no reason to believe that the antenna does not work as advertised, although I will defer to those who know more about the modeling than I do to pass judgement.

While I agree with:

>After some internal debate I decided the >best way to make it easy for others to >build the parasitic reflector was to make a >copy of the driven element and then use >a stub or two turn coil lower the resonant >frequency.

I wonder whether it may be just as easy to stipulate two wooden blocks and make the entire reflector just a tiny bit larger than the DE? Might be easier for some builders. Just a suggestion; the solution you used in the design is entirely valid and useful.

>I used 2 ferrite beads to choke the coax >at the feed, but the antenna IS balanced. >Note that I choke all antennas, balanced >or not.

I agree with the need for the feed-line choke; the antenna is balanced, but the feed line is not. While I normally don't see a need for a balun on an antenna like a dipole, without a balun at the antenna, feed -line radiation and pickup would degrade the pattern and front-to-back ratio a bit. Good engineering choice, IMHO.

> Slight changes in SWR suggest that > there is some minor loss caused by the
> PVC; I would say about 1/2 dB
> approximately.

Actually, I would be surprised if the small amount of PVC used in the design on your page contributed that much loss. If it were lossy, the effect would be to broaden the SWR curve -- the SWR at the band edges would be a bit better than it would be without loss. In actuality, your measurements show a better SWR at the band center and a slightly poorer SWR at the band edges, indicating that the losses are LESS than the model predicted. Could be minor differences in the actual loss of the aluminum wire.

BTW, in another post I mentioned that comparing an antenna over ground to dBd was not correct. That is NOT intended to apply to the information on your page, because your statement that the quad exhibits about 3 dBd gain is correct; the exact gain in dBd can be obtained from the info in your free space pattern and the comparison of an antenna over ground to a similarly polarized dipole over ground at the same height, while technically not dBd, generally does give a dBd gain number close to dBd.

Just some off the cuff observations, not intended to be comprehsive or definitive.

>From: sideband sideband@cac.net

>Chip might have something with the particular arrangements of these
>fractals, however, he has yet to provide comparative data that
>actually means something.

I saw little in the site that I felt was not possible and reasonable, for an antenna of that size.

The point that seems to be undecided is whether the performance of the antenna is related to the fractal aspects or the linear loading obtained by folding the elements as he has done. Would a non-fractal bending of the wire accomplish pretty much the same thing? Might be fun to run it through AO, to see if AO can improve on the gain by making Monte-Carlo type changes to the dimensions. I have no conclusion about whether there is anything magical about the fractals involved, just musing that this seems to be the main point of contention about the design.

>Let's have some data comparing, say, a 10 meter Moonraker 4 with a 10
>meter FQY

That seems like more apples and oranges to me than his comparison to a dipole. Naturally, a physically larger antenna such as the Moonraker would have more gain. His comparison to a dipole in free space does have some validity in antenna engineering circles; dBd is a commonly accepted reference point. Of course, the reference point of dBi is equally universal, and the difference between dBi and dBd is 2.14 dB (or is it closer to 2.13?), both being mathematical constructs. In his using dBd or dBi, you can easily make any such comparison as you suggest.

>or a single element fractal dipole with a standard dipole

That would be a useful comparison if one added a "random" non-fractal antenna of similar overall physical size to the dipole. One can also model a short dipole and see how it compares to a fractal dipole of similar overall maximum dimension. Doesn't seem like it would be very hard for someone to model, if they really were interested. Again, why don't we avoid apples and oranges and compare all of the results in dBi or dBd and avoid the confusion of dBMoonraker or dBfractald. :-)

>Just my two cents.

Now it is up to four cents, unless we are adding up all the posts on the topic, in which case we may have just paid off the national debt. :-)

Seems like only under very specific and limited geometry and freq condx. i.e., more of a pain in the ass than a "strategically located" ferrite core balun is worth. The more hype I read about ferrite core baluns being quick trips to r50 + j0 matches . . If it ain't a 5wpm code test for it all it's ferrite core baluns . . never mind!

Certainly. By definition it ain't a dipole if *all* of the RF doesn't ship
in/out out from the flatop. If I wanted a Tee vertical I wouldn't bother with
any feedline, I'd simply endfeed the lone uprunnner with an MFJ random wire
tuner and hope for the best. Never could figger out whether I preferred the
current node or the voltage node in the shack, both have their charms. Back to
real balanced tuners, annoying clunkers that they are. Tnx Cec.

No argument. I wanted to keep it simple.

It is also the power fed
to the
> antenna terminals, not the power of the transmitter, unless you also
factor
> in feed line loss.

I did say "at the antenna."

> Also, that dBi reference is for the gain of the antenna in situ; ie,
over
> ground, with any other attenuations factored (loss through buildings,
etc.)

If you mean the gain in the presence of the building or ground as
reflected in the pattern, I agree. Are you saying a loss through a
building should be factored into the gain or factored out? If it's an
absorption loss due to material (brick, wood, etc), I think I'd keep
that a separate term.

> As a last point of reference, over "average" ground, a half-wave
dipole up a
> half-wavelength has a gain of about 7.8 dBi. Very interestingly, this
is a
> gain of about 5.2 dBd.

Hmmm... Not to be nit-picky, but there should be a difference of 2.15 dB
between dBi and dBd values. One other point. Sometimes the ERP (the
power at the antenna times the gain of the antenna referenced to a
half-wave dipole) is needed. The value of gain used in the
calculation might then need to adjusted by that nasty little 2.15 dB
term.

>So a half-wave dipole over real ground really
does

Source record: 180362

Couple of comments:

I have the HF9V now and used the HF6V back in the early 80's. Both have been outstanding antennas, not as much from a pure performance standpoint but rather for their combination of reasonable size, rugged construction and multiple resonances at usefull frequencies without lossy and "tender" traps.

Most of the time, the wire antennas here at W5YR will beat the HF9V, but it is worth having in the backyard purely to have a single antenna that will cover - reasonably well - such a broad frequency range. An every now and then, the HF9V will drum up a signal in better shape than any of the others.

And it will likely survive any storm that comes through here so that high winds will not take me off the air. At my age, one doesn't take kindly to tree-climbing!

It is priced probably too high at around $350 these days, but that seems to be the going price for most of the multi-band verticals and Lord knows the HF9V seems to be better constructed and much more rugged than the others. I think that I paid $129 for the HF6V about 1983 or 84.

That said, there are drawbacks and compromises to any antenna. Chief among these for the HF9V is its 3/4 wavelength height on 10 meters. One could not intentionally select a worse antenna length for 10 if there is any interest at all in other than local and nearby stateside contacts. The 1/4 wavelength vertical produces much more useful output at much lower elevation angles, hence is usually to be preferred for DX work.

On the other hand, a ground-mounted 1/4 wave on 10 is not always a world beater. It would have been nice if Butternut could have arranged to have the *top* 1/4 wave section of the HF9V the operational element on 10! <:}

To be honest, I do have to admit that the HF9V does its thing with the aid of 60 ground-mounted radials . . .don't believe any of the propaganda that says radials are not necessary for this antenna configuration.

1)I have stated my stipulations. If ARRL wants to act professionally and responsibly on this and not hit an academic with 'this must be an April Fool article' nonsense, why should I care who reads the MS? The point of peer review is when its incorrectly seen as wrong, the authors get to explain and refute: responsibly and cogently.

2) Right now, I get OVER 250 hits a day AVERAGE EACH on the K2 and FQY pages on the ham page of:

http://www.fractenna.com

In comparison, publishing in a ham magazine with very limited circulation only benefits the publisher; certainly not the author. And universities now make major distinctions between peer reviewed and non-peer reviewed articles. So essentially there is no reason for a professional to publish in a ham magazine anymore, unless there is an option of peer review.

Believe me; peer reviewing is no biggie. If done, all that is needed is a statement in the acknowledgement that the article was peer reviewed.

In other words, in the final analysis, one must understand who is doing who a favor.

Don't you think?

Hi Steve,

I am sure you will appreciate that the greater part of engineering is making a design producible, and marketable. I have also turned from practical designs because they do not further my understanding of the nature of the beast. I did however make an exception for the benefit of those posting here a week ago - but apparently the cult of personality was the real draw to this topic - not practical design.

Still and all, there are many downloading these practical designs from my temporary page even now with a stale link. My ISP provides great metrics service in regard to network traffic to my site and I can track some browsers and their host (the Army appears to be quite interested, that or they are interested in my Oxygen Sensor work or my design of the Flight Data Recorder).

As an engineer, I must say that the fqy solves the construction problem in probably the best manner for such a complex design. Unfortunately all the barbs pointed at your entrant also apply to any implementation of the fqy at 20 Meters (much less lower bands). What goes around comes around.

As I'm sure you're aware, an article does not get published in a peer reviewed scientific journal unless and until all of the concerns and questions raised by the reviewers have been addressed to their satisfaction in the article. That's what 'peer reviewed' usually means. It means you basically place yourself at the mercy of the reviewers. Is this what you're suggesting?

Ed and Steve, let me fill you in on this a bit,

Some consider all the Fractenna posts as "trolling", others have other names for it, but the result is very little technical information is exchanged in direct discussions with Fractenna.

The technical information rate, as a percentage of newsgroup time or kb of file size, is about as low as it gets. But maybe I can speed the exchange up a bit in this thread.

What I have gathered out of years of seriously trying to understand what Chip brings to the table... is this:

The general idea offered is form before function. Chip claims fractals have some unique property that, when used in an antenna and optimized, makes them "unbeatable".

The design system works this way. The "designer" keeps trying random fractal shapes and eventually hits one that sort of fits an application. The designer then uses a computer to refine the shape through a series of trial and error changes until the "form" winds up as good as it can get within certain guidelines.

So far, this has been the technical limit of what has been offered to this group, and to our fraternity.

If you think about what you are not involved with, it disproving his claim that he has optimized the antenna for a certain set of parameters.....and that you can't change his design to make it any better (he hides his desin to prevent that).

As you all know, the way product engineering normally works is the designer looks at all other past solutions in detail and takes the "good things" from each. You can't do that, because the original design you are supposed to beat is hidden.

The gurantee of not solving this conumdrum revolves around the fact a hidden design sets the parameters or limits, and you have to handle

the problem the long way and find something that fits guidelines formed around the "hidden" solution.

When a particular device already defined sets the limits (form before function), it really is difficult to find something that "beats" that device in all parameters. It is time consuming, and there is no reward except the satisfaction of deflating an ego that is intentionally designed to cry for a sharp pin-prick.

For example, Steve suggested one antenna as a small helix formed in a larger loop and Chip sneered at it. The only reason that can happen is Chip set the guidelines around an antenna that he randomly stumbled upon, and refined through trial and error. Where that antenna "wound up" is where the goal has been set, and Steve has to engineer a solution to an equation written by a monkey at a typewriter.

If we change one parameter, like say the frequency, and move it to somewhere in mid-VHF...suddenly Steve's helical loop has huge mechanical advantages. It could be automatically manufactured out of one piece of conductor, and self support. Tooling would be cheap, it would be easy to tune. If we used Steve's loop, and designed the guidelines around it, Chip would have a difficult if not impossible time beating the loop. Unfortunately, the troll sets the guidelines.

We can do that with almost any antenna, there is no magic in any of this. When form preceeds and defines all the parameters, it's difficult to design someting else to "beat it".

In the long scheme of things this entire fractal thing is totally meaningless. No one will lean how an antenna radiates, no one will learn how to fill a defined set of parameters, and we certainly won't learn how to be gentleman or helpful to each other.

With all this considered, the only conclusion I can reach is this is all a giant time wasting troll. We all could be doing more productive things.

On my web page, I have an article about such a dipole published
in Worldradio and reprinted by permission - and it's even
rotatable. There is absolutely no reason why a multiband
dipole cannot be fed with ladder-line (maybe unless one lives
in a rain forest).

Stan
We (Elk Antennas) make a very small 5 element (2 foot boom) log periodic that
can be used indoors because of its small size. I used one (hung from the ceiling

with a harness made from fishing monofilament line) for many years for packet.
As long as you don't get in front(or within 2 feet of the sides) of the antenna
you should have no RF exposure. The SWR is 1:1 across the 2M band and no worse
than 1.4:1 440 to 450 MHz. Gain on 2M was measured at 6 dBd.
If you are at all interested, I'll e-mail directivity plot and photos.
Best wishes de ray, w6fya

Why anybody on a tight budget would consider the B&W is beyond comprehension.
On certain bands, its efficiency is pretty low. Put up a dipole 1/2WL on the
lowest frequency of operation and feed it with open-wire line. That's about
$25 worth of wire that works well on all HF bands. You can find out about
such an antenna at:

Jon- save your money on the B&W and put up a simple dipole with ladder line. Also- get a tuner, because you will need one sooner or later, they are not as lossy as some preach, and it does make life easier.
Making the antennas yourself will be a good step toward self-sufficiency, and - (a little known secret)- a person is far more likely to adjust an antenna he made himself, to get it to work best, than to do the same thing with one designed by an "expert".

Good luck- and do it- Bill- W4BSG

Yuri, K3BU wrote:
"Any known and proven method of doing that?"

Conductivity can be determined by comparing the attenuation on a radial path from an AM broadcast station with the FCC`s published curves for the frequency of the field strength measurements. You find the curve which best fits your measurement data. Each curve is for a specific conductivity in millivolts per meter.

You need a field strength meter, a U.S. Geological Coast and Geodetic Survey map for the area, and a GPS set would be helpful. You need the FCC conductivity curves, of course.

Make Lattitude and longitude marks through the transmitter antenna location on the map. A protractor can be used to plot radials you will explore on the map. Choose and mark likely accessible measurement sites on the map. Many may not work because of conducting structures nearby which upset the radiated field in their vicinity. The closest measurement site to the transmitter should be well into the far field.

Find a lot of sites. Keep good records. Do several radials and several sites along each radial. You will be interested in the field strengths at the water`s edge where the radial crosses the shore on opposite sides. The averages obtained from attenuations along the radials should nail the conductivity of surface of the pond, the prairie, or whatever the groundwave is traversing. Computations can show what attenuation soil of this conductivity will produce at other frequencies.

You can compute penetration from conductivity and freqquency, but what will you do with the penetration information?

Best regards, Richard Harrison, KB5WZI

Chip,

How many hours a day do you spending in this newgroup. I mean that
as a serious question. The sheer number of posts indicates a lot
of lost antenna designing time and on-the-air operating or are you
doing this while on the air?

Yeah. Besides, you should go back through the archives if you want to know what question he wants you to answer for him to know the answer to his question that you don't know that was asked. By him.
Hope this helps. :-)

Paul,
Sounds like you have enough room for a fair sized antenna. One
way would be to put the tuner in the center of a 50' side, giving you
24' + 24' = 48' on each side of the tuner. Thats almost enough for
80 meters, and the tuner should(?) handle it fine. I wouldn't worry
about grounding either side of the antenna.
Any antenna 'near' electric lines (house wiring) is prone to
picking
up noise...
'Doc

I am afraid that I did. Fractenna's repeated disruptions of this NG did seem to manage to accomplish his purpose here -- to be disruptive. There were so many Fractenna posts and responses to same that I may have a bit of trouble finding my post to direct you to it.

The only way I can really think of to end this is to simply ignore the posts and continue to respond to those who post something not related to his failed attempt to end the thread. I was going to change the thread name, but noted that he started in again this morning, so changing the thread name would NOT be ignoring him, so I don't think it appropriate to do so.

I must say that of all of the posts I have seen in 10 years of NG participation, his repetitive tirade was about the least mature. I felt bad enough about my "pot, kettle, black" quip; I can't imagine how he could not be deeply ashamed of his conduct.

> that a separate term.

Of course, if one is trying to do some sort of measurement of the gain of an antenna, ideally, the building wouldn't be a factor at all. :-) If a real world gain, if the building acts to add gain, I would figure it in; if it subtracts, I would figure that in, too. Otherwise, how would one differentiate between a gain change that was as a result of propagation loss through a building and one that is the result of the addition of more "parasitic elements" due to the building, which could just as easily detune the antenna and change the current and phase relationships and decrease the gain (and degrade the pattern) through that mechanism.

I picked a few nits, so you are welcome to do so. I usually round to the nearest 0.1 dB when I give results from EZNEC. Even then, I doubt that there is a full 0.1 dB of precision between the model and reality.

> One other point. Sometimes the ERP (the power at the antenna times the
gain of the antenna referenced to a

might then need to adjusted by that nasty little 2.15 dB
> term.

Yes, I think that the RF exposure regs, for example, exempt repeaters with <500 ERP from the need to be evaluated.

You have seen it all?? Think about someone actually believing this of themselves.

>
> You said you had a spiral for 14 Megs that was 5 inches in size. Tell us
about
> it.
>

I never said I has a spiral. Do you actually read anything? I said I had a helically wound loop and the helix section was 5 inches in diameter and the total wire length was 1.5 wavelengths. I am not sure what your motive is in continualy misrepresenting my statements. I have corrected you several times. The file has 500+ segments. When I get EZNEC Pro, I will run it.

In the meantime, I have no interest in getting sucked into a foolish round of posts back and forth like this is starting to turn into. My random geometry works the same as the MI2 Fractal - deal with it.

73,
Steve

I am sorry, NC, but in a public forum, one is not really communicating with any individual; they are communicating with the group. I can think of no practical way to exclude you from that communication. The ability to do that is under YOUR control, so if you do not want to see my responses to your posts, you are welcome to use your killfile.

>>I think I can see the confusion; a truly "random" design could be resonant

easily
>>discovered possible designs that are sufficiently random.

I do want to clarify one point in the above statement. In the second sentence, "his antenna" refers to the random design offered here by VE9SRB, not to the any of the fractal products. I do not know the extent to which a fractal design differs from a random design; I have not read any paper that really treats the electromagnetics of the fractal design vis a vis other techniques to make physically smaller antennas. The only real data I have read is the posted info of VE9SRB's random design vs the fractal, and I do not feel that his post is enough for me to draw any firm conclusions. After reading my paragraph, however, I realized that my careless use of a pronoun where it was not clear to whom the pronoun was associated. Again, let me make it clear that the above paragraph is made about VE9SRB's random-design post.

2778. Chirps Chilli Contest Challenge

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-21 00:00:00 UTC
From: k3bu@aol.com
Message-ID: <20000921170604.23906.00000209@ng-fs1.aol.com>
Source record: 179930

Notes From An Inexperienced Chili ConTaster Named CHIRP (famous East Coast contester, DXer and best antenna designer ever lived), who was visiting Texas from the East Coast:

"Recently I was honored to be selected as an outstanding Famous Fractal celebrity in Texas, to be a judge at a chili cook-off, because no one else wanted to do it. Also the original person called in sick at the last moment, and I happened to be standing there at the judge's table asking directions to the beer wagon when the call came. I was assured by the other two judges (Native Texans) that the chili wouldn't be all that spicy, and besides they told me I could have free beer during the tasting, so I accepted."

Here are the scorecards from the event:

Chili # 1: Mike's Maniac Mobster Monster Chili

JUDGE ONE: A little too heavy on tomato. Amusing kick.
JUDGE TWO: Nice, smooth tomato flavor. Very mild.
CHIRP: Holy shit, what the hell is this stuff? You could remove dried paint from your driveway with it. Took me two beers to put the flames out. Hope that's the worst one. These Texans are crazy.

Chili # 2: Arthur's Afterburner Chili

JUDGE ONE: Smoky, with a hint of pork. Slight Jalapeno tang.
JUDGE TWO: Exciting BBQ flavor, needs more peppers to be taken seriously.
CHIRP: Keep this out of reach of children! I'm not sure what I am supposed to taste besides pain. I had to wave off two people who wanted to give me the Heimlich maneuver. They had to walkie-talkie in 3 xtra beers when they saw the look on my face.

Chili # 3: Fred's Famous Burn Down the Barn Chili

JUDGE ONE: Excellent firehouse chili! Great kick. Needs more beans.
JUDGE TWO: A beanless chili, a bit salty, good use of red peppers.
CHIRP: Call the EPA, FCC, I've located a RF or uranium spill. My nose feels like I have been snorting Drano. Everyone knows the routine by now. Barmaid pounded me on the back; now my backbone is in the front part of my chest. I'm getting shit-faced.

Chili # 4: Bubba's Black Magic

JUDGE ONE: Black bean chili with almost no spice. Disappointing.
JUDGE TWO: Hint of lime in the black beans. Good side dish for fish or other mild foods, not much of a chili.
CHIRP: I felt something scraping across my tongue, but was unable to taste it. Sally, the bar maid, was standing behind me with fresh refills; that 300lb.

bitch is starting to look HOT, just like this RF nuclear-waste I'm eating.

Chili # 5: Linda's Legal Lip Remover

JUDGE ONE: Meaty, strong chili. Cayenne peppers freshly ground, adding considerable kick. Very impressive.
JUDGE TWO: Chili using shredded beef; could use more tomato. Must admit the cayenne peppers make a strong statement.
CHIRP: My ears are ringing, and I can no longer focus my eyes. I farted and four people behind me needed paramedics. The contestant seemed offended when I told her that her chili had given me brain damage. Sally saved my tongue from bleeding by pouring beer directly on it from a pitcher. It really pisses me off that the other judges asked me to stop screaming.

Chili # 6: Vera's Very Vegetarian Variety

JUDGE ONE: Thin yet bold vegetarian variety chili. Good balance of spice and peppers.
JUDGE TWO: The best yet. Aggressive use of peppers, onions, and garlic. Superb.
CHIRP: My intestines are now a straight pipe filled with gaseous, sulfuric flames. No one seems inclined to stand behind me except that slut Sally. I need to wipe my ass with a snow cone!

Chili # 7: Susan's Screaming Sensation Chili

JUDGE ONE: A mediocre chili with too much reliance on canned peppers.
JUDGE TWO: Ho Hum, tastes as if the chef literally threw in a can of chili peppers at the last moment. I should note that I am worried about Judge Number 3. He appears to be in a bit of distress as he is cursing uncontrollably.
CHIRP: You could put a grenade in my mouth, pull the pin, and I wouldn't feel a damn thing. I've lost the sight in one eye, and the world sounds like it is made of rushing water. My shirt is covered with chili hich slid unnoticed out of my mouth. My pants are full of lava-like shit to match my damn shirt. At least during the autopsy they'll know what killed me. I've decided to stop breathing, it's too painful. I'm not getting any oxygen anyway. If I need air, I'll just suck it in through the 4-inch hole in my stomach.

Chili # 8: Helen's Mount Saint Chili

JUDGE ONE: A perfect ending, this is a nice blend chili, safe for all, not too bold but spicy enough to declare its existence.
JUDGE TWO: This final entry is a good, balanced chili, neither mild nor hot. Sorry to see that most of it was lost when Judge Number 3 passed out, fell and pulled the chili pot on top of himself. Not sure if he's going to make. Poor Yank.
CHIRP: --------------(editor's note: Judge #3 was unable to report)"

And he has the guts to challenge people to contests?
I hope this helps to put CHIRP in proper light.

Yuri wrote:
"---trying to find where is the best RF ground and terrain."

That is related to soil conductivity, alright. I recall checking the salinity of distilled fresh water on my ship in WW-2. The gauge was just a simple ohmmeter with electrodes in the stream of water from the evaporator. It doesn`t take much carry-over of salt to bring the resistance of the water down. But, it doesn`t take much salt to make the solution about as conductive as it will ever get.

The CRC "Handbook of Chemistry and Physics" gives the millimhos per centimeter for various percentages by weight of anhydrous solute between 0.5% and 6%. After 6% concentration is reached, the point of diminishing returns seems to have been reached in increased conductivity. In any case, that`s where the report on salinity and conductivity stops. The extremes are 7.8 mmho/cm and 72.6 mmho/cm. The FCC 5000 mmho/m for sea water conductivity is taken on a cube with 10,000 times the area and 100 times the distance between faces so division by 100 should give the mmho/cm, or 50 mmho/cm, which is better than artificial sea water with 0.5% salinity and 7.8 mmho/cm, and a conductivity that is not so good as 6% salinity and 72.6 mmho/cm.

All measurements were made on artificial sea water as formulated by Lyman and Fleming and reported in 1940.

The point is you are not likely to find a natural saline concentration on earth which is significantly better as a conductor than sea water.

Best regards, Richard Harrison, KB5WZI

2781. CHIRP CHILI CONTEST CHALLENGE

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-21 00:00:00 UTC
From: k3bu@aol.com
Message-ID: <20000921171938.23919.00000174@ng-fs1.aol.com>
Source record: 179933

Notes From An Inexperienced Chili ConTaster Named CHIRP (famous East Coast contester, DXer and best antenna designer ever lived), who was visiting Texas from the East Coast:

"Recently I was honored to be selected as an outstanding Famous Fractal celebrity in Texas, to be a judge at a chili cook-off, because no one else wanted to do it. Also the original person called in sick at the last moment, and I happened to be standing there at the judge's table asking directions to the beer wagon when the call came. I was assured by the other two judges (Native Texans) that the chili wouldn't be all that spicy, and besides they told me I could have free beer during the tasting, so I accepted."

Here are the scorecards from the event:

Chili # 1: Mike's Maniac Mobster Monster Chili

JUDGE ONE: A little too heavy on tomato. Amusing kick.
JUDGE TWO: Nice, smooth tomato flavor. Very mild.
CHIRP: Holy shit, what the hell is this stuff? You could remove dried paint from your driveway with it. Took me two beers to put the flames out. Hope that's the worst one. These Texans are crazy.

Chili # 2: Arthur's Afterburner Chili

JUDGE ONE: Smoky, with a hint of pork. Slight Jalapeno tang.
JUDGE TWO: Exciting BBQ flavor, needs more peppers to be taken seriously.
CHIRP: Keep this out of reach of children! I'm not sure what I am supposed to taste besides pain. I had to wave off two people who wanted to give me the Heimlich maneuver. They had to walkie-talkie in 3 xtra beers when they saw the look on my face.

Chili # 3: Fred's Famous Burn Down the Barn Chili

JUDGE ONE: Excellent firehouse chili! Great kick. Needs more beans.
JUDGE TWO: A beanless chili, a bit salty, good use of red peppers.
CHIRP: Call the EPA, FCC, I've located a RF or uranium spill. My nose feels like I have been snorting Drano. Everyone knows the routine by now. Barmaid pounded me on the back; now my backbone is in the front part of my chest. I'm getting shit-faced.

Chili # 4: Bubba's Black Magic

JUDGE ONE: Black bean chili with almost no spice. Disappointing.
JUDGE TWO: Hint of lime in the black beans. Good side dish for fish or other mild foods, not much of a chili.
CHIRP: I felt something scraping across my tongue, but was unable to taste it. Sally, the bar maid, was standing behind me with fresh refills; that 300lb.

bitch is starting to look HOT, just like this RF nuclear-waste I'm eating.

Chili # 5: Linda's Legal Lip Remover

JUDGE ONE: Meaty, strong chili. Cayenne peppers freshly ground, adding considerable kick. Very impressive.
JUDGE TWO: Chili using shredded beef; could use more tomato. Must admit the cayenne peppers make a strong statement.
CHIRP: My ears are ringing, and I can no longer focus my eyes. I farted and four people behind me needed paramedics. The contestant seemed offended when I told her that her chili had given me brain damage. Sally saved my tongue from bleeding by pouring beer directly on it from a pitcher. It really pisses me off that the other judges asked me to stop screaming.

Chili # 6: Vera's Very Vegetarian Variety

JUDGE ONE: Thin yet bold vegetarian variety chili. Good balance of spice and peppers.
JUDGE TWO: The best yet. Aggressive use of peppers, onions, and garlic. Superb.
CHIRP: My intestines are now a straight pipe filled with gaseous, sulfuric flames. No one seems inclined to stand behind me except that slut Sally. I need to wipe my ass with a snow cone!

Chili # 7: Susan's Screaming Sensation Chili

JUDGE ONE: A mediocre chili with too much reliance on canned peppers.
JUDGE TWO: Ho Hum, tastes as if the chef literally threw in a can of chili peppers at the last moment. I should note that I am worried about Judge Number 3. He appears to be in a bit of distress as he is cursing uncontrollably.
CHIRP: You could put a grenade in my mouth, pull the pin, and I wouldn't feel a damn thing. I've lost the sight in one eye, and the world sounds like it is made of rushing water. My shirt is covered with chili hich slid unnoticed out of my mouth. My pants are full of lava-like shit to match my damn shirt. At least during the autopsy they'll know what killed me. I've decided to stop breathing, it's too painful. I'm not getting any oxygen anyway. If I need air, I'll just suck it in through the 4-inch hole in my stomach.

Chili # 8: Helen's Mount Saint Chili

JUDGE ONE: A perfect ending, this is a nice blend chili, safe for all, not too bold but spicy enough to declare its existence.
JUDGE TWO: This final entry is a good, balanced chili, neither mild nor hot. Sorry to see that most of it was lost when Judge Number 3 passed out, fell and pulled the chili pot on top of himself. Not sure if he's going to make. Poor Yank.

I would say that I am about 5-9 years ahead of others on this topic. From an IP standpoint I am ahead of everyone. And will be for many, many,many years:-)

I can't tell you how many times Bob Hohlfeld and I have listened to other fractal antenna talks and I said :' Bob, what year was that, 93? 95?' It's fun seeing others re-discover. But as it stands there are, oh, a couple (maybe 3)f 'hot topics' left in my opinion ,and these are HARD.

The cream was skimmed a long time ago.

>
>>
>> You said you had a spiral for 14 Megs that was 5 inches in size. Tell us

>> it.
>>
>
>I never said I has a spiral. Do you actually read anything?

Yes.That's what you said in the context of the FRACTAL ANTENNA CHALLENGE. Want
a re-post?

I said I had a
>helically wound loop and the helix section was 5 inches in diameter and the
>total wire length was 1.5 wavelengths. I am not sure what your motive is in
>continualy misrepresenting my statements. I have corrected you several
>times. The file has 500+ segments. When I get EZNEC Pro, I will run it.
>

I don't know why. . . .

5 inches in diameter!

** Yow! **

**What IS this...an IRRIGATION SYSTEM?? A SCULPTURE?? A SKY ANCHOR FOR ROSWELL
RODS?? **

Not only is that a 3D form factor, but an untenable one at that!! No; I guess
I'm NOT interested...who would be?! The weight alone would be prohibitive! Let
alone the mutual coupling at the corners...

Can you imagine going to a customer and saying: I has this wonderful wire-wound
loop on expensive substrate that works as well as a dipole--but is 1/8 wave in
size! It will only cost you 89 clopniks! Then the customer says:'But Fractal
has this flat fractal loop on paper thin substrate for 1/2 clopniks and it
works better'.

Ouch!!!!!!!!!!!!!

>In the meantime, I have no interest in getting sucked into a foolish round
>of posts back and forth like this is starting to turn into. My random
>geometry works the same as the MI2 Fractal - deal with it.
>

That has yet to be seen. So, show me. I will then confirm or disprove, and then
expand on your (incorrect) assertion that it is merely x,y axis symmetry and
wire length that produces such a small, high efficiency, dipole-like antenna.

I am neither inhibited in praise nor critique.

BTW, would you kindly explain WHY you read the rules of the FRACTAL ANTENNA
CHALLENGE, and then misled us into thinking you had something better, when
actually it is a 3D antenna--with 5 inch diameter tubular structure!

Man o man! I am truly blown away!

What a giant step backwards in antenna design!

Ready for the file, as per your offer.

Best,
Chip N1IR

> reduce the gain. 73,

I see nothing in the directivity definitions that stipulate that directivity applies only to free space. One can equally determine the directivity or gain of an antenna over real ground. In those cases, any losses, including the ground loss, would NOT be part of the directivity of the antenna but would be part of the gain.

The formula for directivity is:

D = P / Psubav, where D is the directivity, P is the power density at its maximum point on the surface of the sphere and Psubav is the average power density.

The formula for gain is G = k * D, where k is the efficiency of the antenna, ie power radiated divided by the power input to the antenna. IMHO, one must generally include ground losses and, under some circumstances, other site losses.

In most amateur practice, G ~= D.

This is discussed in the ARRL Antenna Book, among other antenna theory books.

2785. WOW! A QUAD WITH 5 inch DIAMETER COILS AS A LOOP!!

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-21 00:00:00 UTC
From: fractenna@aol.com
Message-ID: <20000921173847.16176.00000148@ng-cg1.aol.com>
Source record: 179937

This has got to be one of the most interesting antennae I have ever heard of!

Take 9 feet on a side of form factor, then compose a square from it. On each side of the square, take some kind of PVC pipe (anyone have a better suggestion?) about **5 inches** in diameter and wrap wire around it. Do this to the 4 sides and attach as a closed loop.

Hey! A nifty small-sized 20M quad loop element!

Advantages:

*Stable! With this much weight, if you can get it in the air, then nothing can get it down (or turn it!!)

* Prominent! Your neighbors will admire the plumbing statue you have erected.

* Charismatic! Just explain that it is a new religious symbol and your house is where it all started!

* White! Brite! Catches the morning sun with that lovely snowy glow and highlight!

* Utilitarian! Explain that its a framework for a new donut shop sign to be erected soon, or the return of Burma Shave iungles.

If you want to make a STATEMENT beyond just getting out a 20M signal, this is the way to go!

Steve, VE9SRB, has the plans. Just ask him today!

From: w1ksz@tiac.net
Message-ID: <39ca80fc.1063554@news.tiac.net>
Source record: 179939

I picked up what looks like a 2 Meter J-Pole antenna. It is
about 20 feet of RG-58 to a Black cylindrical "Balun" to
about 5 feet of Twinlead. The twinlead has a breal in one side
about a foot up and the end of the twinlead is shorted, with a
nylon loop for hanging up on something. The "Balun" is marked
"Radio Engineers".
Anyone ever see one of these ? Who made it ?

You will like EZNEC better than NEC. It is a LOT more user friendly. :-)
If memory serves, you can pay your money with a credit card and download it
from his site, so you could be up and running very quickly.

> The randomness of which I speak is in regards to the shape of the antenna.

> antennas are essentially the same.

First, of course, this is a sample of one, so I don't think we can draw any
firm conclusions from your work yet. And, as Chip points out, your model did
not include the ohmic losses of the wire, although that is probably not a
major factor. Did you compare the currents on each of the segments from one
antenna to the other? If the currents are pretty much the same, then the
ohmic losses will probably be relatively unimportant. But you never know,
and including the losses would be the best science, so I would hope to see
it done at some point.

As an experienced antenna designer, I am sure you are aware that the
performance characteristics of an antenna include gain, F/B, SWR bandwidth
and other bandwidth related factors such as how the F/B varies across the
usuable bandwidth, etc. The latter may very well be the major difference;
the 25 dB model that Chip posts on his web site looks pretty good for a
2-element quad, so I would like to see how it compares between the fractal
and random designs and now it varies with frequency between the fractal and
random designs.

Were you serious about publishing the results in the IEEE antenna
transactions journal? If so, perhaps the fractal vs 4 random designs, with
lots of graphs, would be adquate. I believe their journal is peer reviewed,
so the science should be as rigorous as possible or it will probably be
rejected.

I look forward to your work and any references to any theoretical treatment
(by you or others) that might explain the theoretical reasons a fractal
design would be superior to randomly chosen configurations. (Chip, I lost

the reference to the paper by Cohen and ? that you posted. If there is a URL for it, can you repost or email to me at my AOL address?

The performance data, while it could be more complete, is a bit more than most antenna manfacturers offer, so do see it in that perspective. I think what you have been asking for is more theory about the concept of fractal design and just how it functions.

> I also agree that 3 dBd is an improvement over a dipole, and the F/B

I am confused. Fractennas published data includes a radiation plot of his fractal antenna. This could be very easily compared against other published radiation plots, or those derived by modeling. Just because he chooses not to publish the plots of Yagis, for example, does not mean that the comparision you seek cannot be easily done -- by you, of course. :-)

>Would you expect Michael Johnson go and play seriously against school kids?
>Hmmmm? It would be below his dignity.

Michael Jordan has skill and he proves it every time he plays.

What you do is press a voice keyer, look at CT, press a function on your keyboard, turn a knob, and occasionally blurb something into a microphone. Some skill!

IF you run like MOST so-called 'contest stations', you are using power exceeding legal limits for your respective country; splitting the feed with multiple amplifiers to point at more than one direction at once (also illegal)with multiple antennae; and jumping on top of others at any cost to get multipliers. That's for starters.

I do none of these things--although this year I WILL use my first voice keyer and computer log.

I will beat you hands down in the LP phone category because I know how to lust for, and grab those contacts and how to use the best antenna for my situation. Just ONE I might add...

>to the 4 sides and attach as a closed loop.
>
>Hey! A nifty small-sized 20M quad loop element!

Beware ... Byrnum Woods may be marching on Dunkirk Castle! Chuckle.
May not be so these days, but long ago and far away I tried PVC pipe for
a 40 meter shortened antenna like this! Surprise! Le' PVC, he gettum
hot with my KW source! Dunno if same story now, but -- some -- forms of
good old PVC aren't so swift as a coil form! They soak up RF .. or at
least that is what I found out back then!

When I mentioned this long ago and far away in the FidoNet ham readio
echo, pre-Internet, the conclusion was test the PVC before you do the
job! One poster said you could put it in a microwave oven and if it got
hot you had your answer, but I never tried it in my original Amana Radar
Range!

I simply abandoned the idea of PVC as the form and forgot the idea...
Maybe is not true any longer, but someone here who has more recent
knowledge will be sure to correct me if I'm off base! ;)

--> Sleep well; OS2's still awake! ;)

I would wager that 99% of the antennas that have been published in ARRL publications have not been so tested. The claim of 3 dBd gain appears reasonable; on what basis would you suggest that anything past NEC-4 modeling would be required? Like all antenans, the fractal quad has its advantages and disadvantages, and, like most antennas, most of those are in the eyes of the beholder.

Now, if your really want to see it compared to a similar antenna at one of the VHF antenna contests, build a 2M or 6M version and submit it. I am sure that this NG, and certainly including Chip, will be interested in the results. But I would disagree that such measurments need be made before publication in QEX.

Now, I don't know that claims that Chip will make in that article vis a vis the fractal design, but even if it were demonstrable that a "random" design of similar size could have reasonably equal performance, the design I saw on Fractenna's web page offered some mechanical advantages that would make it worthwhile. QEX is intended to publish articles that encourage experimentation, and the fractal quad certainly qualifies as an experimentation opportunity. Maybe the QEX article could contain some of that theoretical treatment we have been all hoping to see. To survive the peer review that Chip said he would like to see, the article would certainly have to have a supportable explanation of how it works.

I look forward to seeing it, Chip. Having been involved in some of these discussions, I will offer to Doug that I would like to offer my input.

If Chip would use the same process to write his article as I use for mine, he will send a copy to his "hand picked" peers, who will give Chip feedback that will make his article more accurate and useful. An author would generally do that anonymously in that he would not air each comment received from each reviewer, although a good author will have an acknowledgment paragraph. The ARRL editorial staff often sends articles out for review by knowledgeable outside experts in a particular subject and ARRL does not air each comment received from each reviewer. Is this "concealed?" Was it "concealed" when I did this in conjuction with many of my articles and books?

What will really count is that the end result will be better for the additional input. I appreciate Chip's willingness to seek the input of other antenna professionals.

I've heard of other cases of that. When I made coils for a 160 dipole I used pvc. Someone had mentioned somewhere to use the "grey" type pvc instead of the white, so I went with that. I gave it the microwave test, and it stayed cold. I don't know if using a lower frequency could be worse, but they seemed to do ok on that dipole, and I've also made 80m mobile coils from it for plastic bugcatcher use. Worked fine here, but only run 100w. I think a standard coil form would be better, but not very realistic to try to make something like that here. I don't have the tools needed. So I have to make do with the PVC. I've also used just plain plastic tubes, but never tested for heating. MK

Chip's claim for his antenna in a recent post is:

> This antenna provides a unique combination of ease of construction, optimum
> performance, and dinky form factor. It is NOT MATCHED in performance,
> simplicty, and reliability by any other such small antenna in that form factor.
> None.

I think that his antenna has yours beat in "ease of construction," Steve, so if the gain is equal, his combination is still better than yours. I would find it easier to cut a mess of PVC to the same size and glue them all together than to cut them to random sizes.

Dear Yuri, I don't think you've got the message yet - if there's any salty water around, just erect a vertical and call CQ contest.

Not even YOUR S-meter needle, plus a microscope, is sensitive enough to detect a difference of 1/500th of an S-unit between high and moderate water salinity.

Yuri, you leg puller. ;o)

Are they that desperate for material?

Maybe I'll offer up something on buried dummy loads. Low (really low) profile, compact, low cost, wife-approved, wide bandwidth, excellent SWR, easily meets the FCC field strength safety requirements.

Then for a follow-up article I'll show how to feed one with ladder line.

I love it... a whole new post-retirement writing career.

Ed:

I assumed you looked at the EZNEC files - is this true?

With the MI2 loop, you would need to cut 100 sections. They may not all be the same size (I would need to see his model).

With mine you would need to cut 84 sections. They are not all the same length.

Now take a look at the number of wire bends if you were making either antenna out of a single piece of wire.

Also, ease of construction has not been my issue. The relative performance and the merits of the fractal geometry have been my issue. When I look at either antenna, I do not think either offer the claim of "ease of construction"

2817. HF9V Grounding?

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-21 00:00:00 UTC
From: VE7WVG@home.com
Message-ID: <39c94bdc.161049048@news.crdva1.bc.wave.home.com>
Source record: 180009

I have a couple of questions regarding grounding. I have read over all the threads regarding grounding in this forum and also my instruction manuals for my HF9V and CPK counterpoise kit.

I am mounting a HF9V on top of a 48 ft tower which I also have mounted a tri-band beam.

1stly, with the CPK counterpoise kit installed on my HF9V, should the antenna be insulated from the mast and tower seeing as I have the counterpoise kit installed and it is acting as an artificial ground, or should i also have my tower ground wires clamped to the mounting post or the shield side of the feedpoint of the HF9V?

2ndly, I have seen much talk of ground radial systems for grounding the HF9V when installed on the ground. However I am curious as to whether it matters if these ground radials are bare wire or insulated like any scrap household wire you may have lying around.

3rdly, Is it important as to what depth these ground radials be burried? I know most people put them 1" - 4" deep, but if they are deeper does it matter will performance suffer, high swr etc?.

4thly, does it matter what guage these wires are? Is thicker wire better than thinner wire?, I know more radials seem to be better than less, but what about the thickness of the radial wire?

Lastly, would a ground radial system be effective for an electrical ground of my tower. Are there advantages/dis-advantages to this sort of tower grounding or is it not at all necessary?

I am finding there is much to learn about grounding systems, and so far from what I have found, its pretty interesting stuff.

Please respond to this newsgroup so that others may learn as I am from reading the posts here, but an email reponse would be appreciated also:

For Auction on Ebay...

COMET CH-701X Miracle Boy II Wide-Band Antenna for HT, or Scanner Radio!
144MHz (2dBi gain), 430MHz (3.4dB), 900MHz (5.5dB), 10W, 50 ohms 18-3/4"
overall length, 11-3/4" from base is rigid, with remaining 7-1/4" flexible,
small loading coil in the middle. Standard BNC connector at base. This is
Brand New, cost $54.00!

About 25 minutes left, going at only $10.50 so far.

Click here:
http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewItem&item=441456216

Thanks,
Bill Crocker

>But what if he references it to a real dipole near the ground? Which
>already has 5+ dbd? I think that this is the issue which was trampled
>here in excretia several months ago.

In general, if the antenna is horizontally polarized (I believe it is -- Chip?) and he references the antenna to a half-wave dipole at the same height, the answer will generally be pretty close to the answer he would get comparing his antenna in free space to a dipole in free space.

I think that the EZNEC model he shows on the Web page is of his antenna in free space (although he has not clarified that yet; he isn't talking to me) and that the dBd reference is probably to a dipole in free space.

>I have gotten the impression that comparisons were made and reported
>elsewhere between near-ground-mounted antennas but reported in terms of
>dbd and dbi without making it clear that the ground-enhanced gain had
>been accounted for.

Later in the page, he does reference his antenna over ground and compare it to a dipole at the same height, but the answer of 3 dB is about right for an antenna of that physical size and, although technically a misuse of dBd, it is not misleading, IMHO.

Now, this wouldn't necessarily apply to all antenna types. For example, a very low antenna, ie, <0.05 lambda, for example could show considerable variations between antenna types because of the interaction of the fields with lossy earth. A very small loop, if efficient, would probably come in near about 1.64 dBi in free space, compared to a dipole's 2.15 dB, but if those two antennas were very close to the ground, the small loop would lose gain faster the dipole because the loop has higher fields near the antenna.

>Ed, how about some Socratic wisdom in this area?

Far from Socratic; especially on this forum, I am more the student than the teacher. :-) I will gladly defer to those more wise than I. Besides, if I remember my history, Socrates and Aristotle got a lot of it wrong. :-)

>QTH. He has about an acre of clear, flat, marshy terrain.

Had I done the testing at that location and the results agreed pretty well with the modeling, I would feel comfortable with the result of 3 dBd. His page had given a measured 20 dB of F/B, in reasonable agreement with the model result he posted. I don't know how well that F/B will hold up across the band; in my modeling experience, small antennas have tended to be very sensitive for F/B across the usable SWR curve, but all in all, it does not look like a bad antenna to me.

Both legs of the flat-top on the G5RV are the same length, so it won't matter at all which leg goes to which output connector on the balun. The balun SHOULD be a 1:1, if I remember the G5RV design correctly. The balun is generally used where the coax joins the open-wire line section. A choke balun (current balun) would be the best choice.

Message-ID: <39c96744@turakina.six.asn.au>
Source record: 180018

I originally did this when living in a flat. Mine was for two metres only though. It is exactly like the one described on the web page below EXCEPT I shorted the wires across the top. I am told this takes out some of the reactance in the match point and makes matching easier and more stable. Mine was not in a PVC pipe untill recently and I just hung it from a curtain when in the flat. This is a VERY portable antenna (you can roll it up and put it in your pocket for example).

It has handled more than 100W without showing any hassles for me - although the feedpoints are quite close.

I reckon the J-Pole is just about the best all purpose 2m antenna available. That it doesn't require a ground plane makes it ideal for many applications and it has a little more gain than a quarter wave ground plane (although gain may not be desirable in some circumstances - when working satellites for example)

I have since bought a house so I put it in a PVC pipe and it now hangs about 60' high in a gum tree. After reading the article on the web page you point to I tried it on 70cm and got an SWR of about 1.4:1 (I have about 3db cable loss though so the real SWR may be closer to 2:1).

>I think 3dBd is probably a reasonable gain for any half-size antenna I guess there is so much noise accompanying the good data that it gets lost in the background. Thank's for reminding us Ed.<

Here's something else to consider. Most compacts are used in roof-top installations, so I personally believe weight becomes an extremely important design consideration. This only makes sense! The lighter you make 'em, the higher you can mount 'em using low-cost readily available TV hardware. And, the higher you can mount 'em, the better they work!

I've built and written up several feather-weight designs made specifically for roof-top installation over the years and never lost an element to wind or ice (a falling 3" tree limb took one out a couple years ago). Of course, the undisputed gold-medal winner in the bantam-weight catagory is Mike Traffe's rugged little 10-M monoband Hexbeam weighing a mere 12 ounces!

The salient point being, any compact antenna targeted for a roof-top installation probably requires special treatment that is different from what we'd give a full-sized yagi destined for installation on a 100-foot tower at a contest station.

The question is, if you fail to consider the application, or even fail to consider the antenna's weight at all, have you really completed your design? Food for thought (and it's almost lunch time!)

Certainly plastic dowels Rick; I chose to use PVS because that's what people
like to use.

The antenna 's weight is in PVC. If , say (in this case) 8-9 lbs is too much
for an antenna that WITHSTOOD A TORNADO, then you provide a better one:-)

In that form factor too!

P.S> The hexbeam is 4 times the area...too big a turning radius. WOuldn't want
to upset my good neighbors with an OBVIOUS antenna!

Hi Steve,

I see you now fully perceive the small picture with your last
statement (one of the few to escape the tar-pits). The participants
lost in LaBrea are nameless, their contribution is buried in the
sludge of secrecy, and their hopes will be mired by a judge who is
also a beauty contestant. All in the name of keeping the fragile
participants safe from the corruption of this venue. Such posturing
and manufactured crisis from Fragile Antennas amounts to the squeals
of synthetic virtue.

I applaud your work and effort. Your experience of trying to discern the merit of fractal geometry is performed with the necessary methodical and patient examination. In most venues this is known as the "scientific" method - a bulwark being eroded in some schools it seems (its a shame we have students being taught by those who cannot spell - perhaps a new best selling book will appear "Why Teacher Can't Read").

I find your two examples of random designs matching claims of fractal designs not unfamiliar. I too attempted what I called my "Anti-Fractal," but was unable to worsen performance by dashing the fractal geometry against the wall. Perhaps I may publish that, but it does not serve any purpose beyond the observations already made by you.

I also found that simple deconstructions of fractals reveal characteristics very similar to the original designs. Hence, the notion that there is something inherently better about being "fractal" is simply that, a notion. I suppose academe can provide references and volumes of papers that prove otherwise (on the shelf in the library next to those studies that demonstrate bees can't fly).

I am sure that through the process of sifting candidates and constraining competition, that this so-called challenge will result in nothing remarkable. The process reveals that shallow agenda and is myopic to the larger world's view that it is the participants that bring credibility to an event - not the "award." Your participation in the "shadow challenge" has demonstrated far more credibility and it being ad hoc within an existing venue proves that free dialog and open communication is the value and reward.

Thanks for the positive and engaging writing you have offered following Roy's plea for you to stick around and participate. Your contributions have eclipsed those of the fractal variety.

Yuri, K3BU wrote:
"I am after finding the "bestest" salt water conditioned ground and expanding on their work."

This has already been done by the FCC, which has published its results. Conductivity of seawater is considered near perfect and UNCHANGING at 5000 millimhos per meter. Other soil conductivities are considered less perfect and can undergo change, especially where the ground freezes during the winter.

It is not necessary to resonate a ground connection to the nearby sea. If the sea is near, it is necessary to have a good ground system for a permanent station the same as is used for inland sites. This standard radial system has so much soil cross-sectional area at its periphery that its resistance to the sea will be small. That is why you don`t see medium wave stations clustered at the seaside.

Best regards, Richard Harrison, KB5WZI

The simple answer to that question is, "the antenna you're using
on the air." No antenna on the drawing board or in the shipping
carton is making as many contacts as the one you have actively
on the air. So put *something* up (everything works), and get on
the air. Any antenna you're using is better than one you're not.

> Chip N1IR

I converted my NEC4 input files over to EZNEC and ran the calculations again so that I could provide gain numbers for both antennas. As stated above, Dr. Cohen does not believe the random geometry configuration that I came up with could be as efficient as the MI2 Fractal Loop.

Just to recap: One antenna is the MI2 Fractal Loop that Dr. Cohen described in the his Comm Quart articles. This is the same antenna identified in his $1000 Fractal Antenna Challenge thread. The second antenna is a random geometry (non-fractal) configuration that I believed would have similar performance characteristics as compared to the MI2 Fractal Loop. Note that both antennas have the same wire length and occupy the same physical aperture.

Results:
MI2 Random

Resonant Frequency: 15.15 MHz 14.83 MHz

Resonant Resistance: 28 ohms 27 ohms

Gain (Cu wire): 1.83 dBi 1.83 dBi

The best solution I've found for this problem is to slip pieces of thin wall
poly pipe over the antenna elements. Bird lands, pipe rotates, bird falls off.
Funny as hell.

So, go publish it. If it's a RANDOM design, then it is a fractal one. Best case scenario is you have a fractal design equivalent to the MI2. But that is yet to be seen. SO publish it.

Remember: the objective of the FRACTAL CHALLENGE is to come up with something BETTER.

You haven't entered the FRACTAL ANTENNA CHALLENGE, presumably because you don't have a winner:-)

So far 10 entries have been received. Unfortunately no winners, at least yet.

Also, I notice that you fail to recant your statement about an ARBITRARY design.

I have already made over 100 designs in that form factor that my GA has ARBITRARILY chosen, that don't beat or are not as good as MI2.

Your isn't either--at least from what you claim here.

Let me try again to paint better picture:
We are comparing ocean salt water vs. salt water marsh, where tide might fill some "lakes" in ground, tide goes out, water stays there, sun shines, water evaporates, salt concentration increases, "ground" gets more salty. Is it appreciably better than "regular" salt water? I am looking here at the far field ground, nothing to do with replacing radials with salt.
No concerns about winter, I am looking for ideal place for portable contest operation - trying to find where is the best RF ground and terrain.

K6SE operated one 160m contest from dried out salt lake in the west. Had good results.

Chip:

I ran the two antennas through EZNEC so that I could present gain numbers
for you. Here's the comparison between the MI2 Fractal Loop and a random
geometry. Both have same wire length and aperture size.

MI2 Random

Resonant Frequency: 15.15 MHz 14.83 MHz

Resonant Resistance: 28 ohms 27 ohms

Gain (Cu wire): 1.83 dBi 1.83 dBi

Have a nice day.

73,
Steve VE9SRB

Depends what are you after? Do you want to just drive to work, haul the ton of bricks, or race Ferraris?

Antenna has to satisfy the operator's requirements (propagation, location, purpose DX/contest/yak-yak), fit his budget, etc.
Antyhing radiates, from light bulb, through Fractals, tribanders, monobanders, killer arrays, Razors, ...?
It is as wide open question as "which car is the best."
More precise Q?

Source record: 180041

At the risk of opening this whole topic again, let me clarify what I said.

My statement was strictly in reference to the definition of the term "dBd", and has nothing to do with the legitimacy or usefulness of comparing antennas to dipoles. It is certainly legitimate and useful to compare the gain of a Yagi at 60 feet with a dipole at 60 feet. The danger is in simply referring to the Yagi's gain as "XX dBd", with "dBd" meaning this gain ratio. There are too many people, like Ed, the ARRL, and various other amateur publications that simply define dBd as being 2.15 dBi. The result would be misinterpretation, to the tune of 5 - 6 dB, of what should be a valid comparison.

It's also legitimate and useful to compare the free space gain of a Yagi to the free space gain of a dipole, since both have similar elevation patterns at low and moderate angles, and so will have similar relative gains when both are elevated to the same height. Here, there's no ambiguity.

I feel that people espousing both definitions of dBd were very short on citations of its use, and made their points by being more loud than convincing. And I stand firm in my conviction that whenever it's used, there's a large amount of room for misinterpretation. The use of it you just proposed is different from Ed's and the ARRL's definition and use, which serves to illustrate the problem. There's no problem with using the term, however, provided that you carefully state just what it means each time you use it, as I suggested in my original posting.

> the feedpoint resistance, Pradiated is the power delivered to the feedpoint
> radiation resistance and Ploss is the power delivered to the feedpoint loss
> resistance.
> . . .

The key word here is the third from the end, "feedpoint". I'm pointing
it out because it might have gotten a little lost in that lengthy but
excellent presentation. When using the common equation Steve refers to,
it's essential that both the radiation and loss resistances be referred
to the same point. Failure to do this is the cause of mistaken claims
about folded monopole efficiency and the efficiency of other antennas.
Steve is, of course, doing it right, and in this case illustrating the
calculation with both quantities referred to the feedpoint, a common
procedure.

>Does this mean the thread is now closed?

No; it does not refer to a time-specific event which ended last week.

I, for one, want you to explain what you mean by "arbitrarily chosen".

The best I can figure is that you have found, at considerable effort, another fractal (yes; randomly shaped antennas are fractals...) which has similar but not better performance FOM than the MI2 I have previously published.

This is most certainly NOT a general property of axis-symmetric, random fractal loops--which is what you assert. I proved that to myself, oh, 8 years ago.

The entire point of the FRACTAL ANTENNA CHALLENGE is to find a better performer. You tried, and failed, but you learned a lot about the benefits of fractal antennas and that is a very,very good thing.

I for one would like a copy of the EZNEC file, so I can give you my comments on it. Please send the file as an e-mail attachment, as per your public offer to provide same.

I alos want to know what you found for the gain and field strength of your 5 inch spiral, which you claim has a radiation resistance of 30 ohms--but is very,very electrically small.

I applaude your effort.

2861. Help with random Wire with AH4

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-21 00:00:00 UTC
From: paulmac913@my-deja.com
Message-ID: <8qdjk1cci1@nnrp1.deja.com>
Source record: 180053

I just purchased an Icom 706MKIIG, and the AH-4 Automatic tuner.

I'm limited to attic space for my HF work. The attic is 50' by about 24' wide (on the floor). I'll be running 9913 about 25' from my shack up to the tuner. This is my 1st attempt at this, so please bear with my newbie questions...I'm attempting to get the best performance across as many bands as possible including 6m. 6m is important to me right now because I haven't earned my General privs yet...House is about 400' ASL.

1)Given my available attic space, what length wire should I use on each side of the tuner?

2)Should it be 2 25' wires on each side of the tuner, with the tuner mounted in the center of the attic? Maybe a loop?

3) I'm in a 2 story home, with the attic above. Does the ground side of the wire have to be physically grounded? If so, how?

Thanks in advance...

Yuri may believe that he is God's gift. But I just got a call from one of his competitors who wants me to use his station in the 10M contest.

To beat Yuri on his own terms.

I turned him down, for the simple reason that I have responsibilities and don't expect to be on more than 20-24 of the 48 hours.(I can't go elsewhere to take care of them.)

But boy, he had some comments about Yuri!

Have you talked to your 'friends up in the lofty clouds' recently Yuri? You may get a very different picture if you asked them for some constructive criticism....

I look forward to competing with you.

Sounds like you have lots of room to put something up. I'm partial to homebrew wire dipoles myself. They're cheap, easy to install, and they work. The ARRL handbook has the formulas for dipole lengths in feet which is 234/frequency. So for 6M and a center frequency of 50.05Mhz, 234/50.05 = 4.675 feet on each leg of the dipole. Your attic size sounds ideal for a 20M dipole and even a 40M one if you bend it into a U shape. GL es 73

I've always felt dbd when used randomly should always be in free space. The use of dbd over earth is valid for sure, but confusing as heck to anyone unaware of this use that happens to want to compare a certain antenna to another one on paper. Myself, I only use dbd in free space when stating the gain of an antenna on say this NG."If not dbi". That way it can easily be compared to others in free space. If I stated the gain of say a low dipole at 7.5 dbd over real ground, it's fairly useless for anyone except me. Unless I tell them, they don't know how high, how good a ground quality, etc, etc. So unless they get real lucky, trying to compare that antenna to say a yagi, will likely have quite a bit of error. I think db over earth real handy for local site comparisons, but for describing the gain of antennas on a public forum, I'll always use dbd in free space, if not dbi. dbi being prefered. The real key to my preferring dbd/free space, is it's easily converted to dbi by subtracting 2.15. So to me they can be easily interchanged. IE: 0 dbi = -2.15 dbd. Very clear and easy to deal with. Throw in the ground effects, and it all goes out the window,unless like you say, I include all the other pertinant data. I try to use dbi whenever possible. MK

Hi Bob, thanks for the interest in Reflections 2. The entire manuscript has been proofed and is now being put in page format at the publisher, which is Worldradio Books. It should be released for printing soon, but I have no specific date as yet.

It contains a lot of new information that I believe will interest the ham community, including one chapter that analyzes the operation of RF power amplifiers.

I'll keep the NG posted when release is imminent.

Walt, W2DU

2870. Chirp's Frektal Chilli Contesting

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-21 00:00:00 UTC
From: k3bu@aol.com
Message-ID: <20000921144908.22888.00000089@ng-fq1.aol.com>
Source record: 180062

Notes From An Inexperienced Chili ConTaster Named CHIRP (famous East Coast contester, DXer and best antenna designer ever lived), who was visiting Texas from the East Coast:

"Recently I was honored to be selected as an outstanding Famous Fractal celebrity in Texas, to be a judge at a chili cook-off, because no one else wanted to do it. Also the original person called in sick at the last moment, and I happened to be standing there at the judge's table asking directions to the beer wagon when the call came. I was assured by the other two judges (Native Texans) that the chili wouldn't be all that spicy, and besides they told me I could have free beer during the tasting, so I accepted."

Here are the scorecards from the event:

Chili # 1: Mike's Maniac Mobster Monster Chili

JUDGE ONE: A little too heavy on tomato. Amusing kick.
JUDGE TWO: Nice, smooth tomato flavor. Very mild.
CHIRP: Holy shit, what the hell is this stuff? You could remove dried paint from your driveway with it. Took me two beers to put the flames out. Hope that's the worst one. These Texans are crazy.

Chili # 2: Arthur's Afterburner Chili

JUDGE ONE: Smoky, with a hint of pork. Slight Jalapeno tang.
JUDGE TWO: Exciting BBQ flavor, needs more peppers to be taken seriously.
CHIRP: Keep this out of reach of children! I'm not sure what I am supposed to taste besides pain. I had to wave off two people who wanted to give me the Heimlich maneuver. They had to walkie-talkie in 3 xtra beers when they saw the look on my face.

Chili # 3: Fred's Famous Burn Down the Barn Chili

JUDGE ONE: Excellent firehouse chili! Great kick. Needs more beans.
JUDGE TWO: A beanless chili, a bit salty, good use of red peppers.
CHIRP: Call the EPA, FCC, I've located a RF or uranium spill. My nose feels like I have been snorting Drano. Everyone knows the routine by now. Barmaid pounded me on the back; now my backbone is in the front part of my chest. I'm getting shit-faced.

Chili # 4: Bubba's Black Magic

JUDGE ONE: Black bean chili with almost no spice. Disappointing.
JUDGE TWO: Hint of lime in the black beans. Good side dish for fish or other mild foods, not much of a chili.
CHIRP: I felt something scraping across my tongue, but was unable to taste it. Sally, the bar maid, was standing behind me with fresh refills; that 300lb.

bitch is starting to look HOT, just like this RF nuclear-waste I'm eating.

Chili # 5: Linda's Legal Lip Remover

JUDGE ONE: Meaty, strong chili. Cayenne peppers freshly ground, adding considerable kick. Very impressive.
JUDGE TWO: Chili using shredded beef; could use more tomato. Must admit the cayenne peppers make a strong statement.
CHIRP: My ears are ringing, and I can no longer focus my eyes. I farted and four people behind me needed paramedics. The contestant seemed offended when I told her that her chili had given me brain damage. Sally saved my tongue from bleeding by pouring beer directly on it from a pitcher. It really pisses me off that the other judges asked me to stop screaming.

Chili # 6: Vera's Very Vegetarian Variety

JUDGE ONE: Thin yet bold vegetarian variety chili. Good balance of spice and peppers.
JUDGE TWO: The best yet. Aggressive use of peppers, onions, and garlic. Superb.
CHIRP: My intestines are now a straight pipe filled with gaseous, sulfuric flames. No one seems inclined to stand behind me except that slut Sally. I need to wipe my ass with a snow cone!

Chili # 7: Susan's Screaming Sensation Chili

JUDGE ONE: A mediocre chili with too much reliance on canned peppers.
JUDGE TWO: Ho Hum, tastes as if the chef literally threw in a can of chili peppers at the last moment. I should note that I am worried about Judge Number 3. He appears to be in a bit of distress as he is cursing uncontrollably.
CHIRP: You could put a grenade in my mouth, pull the pin, and I wouldn't feel a damn thing. I've lost the sight in one eye, and the world sounds like it is made of rushing water. My shirt is covered with chili hich slid unnoticed out of my mouth. My pants are full of lava-like shit to match my damn shirt. At least during the autopsy they'll know what killed me. I've decided to stop breathing, it's too painful. I'm not getting any oxygen anyway. If I need air, I'll just suck it in through the 4-inch hole in my stomach.

Chili # 8: Helen's Mount Saint Chili

JUDGE ONE: A perfect ending, this is a nice blend chili, safe for all, not too bold but spicy enough to declare its existence.
JUDGE TWO: This final entry is a good, balanced chili, neither mild nor hot. Sorry to see that most of it was lost when Judge Number 3 passed out, fell and pulled the chili pot on top of himself. Not sure if he's going to make. Poor Yank.
CHIRP: --------------(editor's note: Judge #3 was unable to report)"

And he has the guts to challenge people to contests?
I hope this helps to put CHIRP in proper light.
(With apology to original writer.)

Source record: 180063

>>The question is, if you fail to consider the application, or even fail to consider the antenna's weight at all, have you really completed your design?<<

>Certainly plastic dowels Rick; I chose to use PVS because that's what people >like to use.

My observation was directed more toward Ed and other NG readers as a general comment about compact roof-mounted designs vs. hunky tower-mount antennas. It really wasn't aimed "at" the FQY. I'm sure everyone is aware the FQY is an experiemental design.

As a practical matter, I couldn't use a PVC version of the FQY here because it would almost certainly bring down my skinny 40 foot mast in the first frontal passage to come across the lake (like the one occurring right now with gusts to 45 MPH). Consequently, I use a 3-pound 3-element short-boom yagi that delivers 5-6 dBd gain at a weight my mast can handle safely. I realize a production-engineered FQY would probably weigh far less than 9 pounds, and a production-engineered version of my 3-pound beam might weigh somewhat more.

>P.S> The hexbeam is 4 times the area...too big a turning radius. WOuldn't want to upset my good neighbors with an OBVIOUS antenna!<

I can't agree that's a fair criticism of Mike's antenna. The Hex is flatter in profile, and the one I built with wooden spreaders was virtually invisible against the trees (far less obvious than the Moxon). If the Hex has faults, being overly conspicuous sure isn't one of them.

>P.P.S. How's that EIRP calculation goin'?

Hadn't given it another thought. Did measure true PEP output and line loss, though, so I know with certainty how much power is reaching my antenna terminals.

Rick K1BQT

PS: Ever notice how much smaller ALL antennas look when you double the mounting height?

Don't have to. However, if you are of the opinion that all loops of a given length of wire can produce oodles and oodles of antennas with the same resonance and efficiency and gain and directivity, then you are wrong. It would make an interesting paper though. Why don't you publish it and then others can publish papers showing your errors.

Last year there was a paper on meander loading which made outrageous claims on efficiency (in Transactions) that even we on this NG showed to be wrong. So I guess there is room for false assertions.

Not necessarily. If one has gain, one must have directivity, but it is entirely possible to have directivity but no gain. Most beverages and loopstick antennas are two examples.

"Gain" is probably by far the more useful of the two terms in most antenna-related contexts.

Hi Ed,
This is really a question of definition. In the previous post, gain was defined as the directivity times the efficiency. The gain, whatever it is, is always less than the directivity. It may not be correct to say that an antenna with a "gain" of -23 dBi actually has gain, but that's what it's called. (Can you imagine the confusion in saying the antenna has a loss value of 23 dBi?). My quibble was with the statement that including ohmic loss results in a directivity. It results in a gain. There also may be other losses, such as ground losses, etc. that further reduce the gain. 73,
Bill N3WK

I notice reading in one of Bill Orrs antenna books he mentioned that
Bell labs ran a study in 1932 to find the best ship to shore radio
setups. According to their tests, for over water use, the closer the
shore station to the water the better. They tested using 66 and 33
meters, along with a few other freq's between 40 and 20 meters in the
day. They had ships at sea out to 2500 miles, and many distances in
between. The 66 and 33 m tests showed an 8-12 db attenuation at a
distance of one mile inland compared to a station on the beach/water.
Now, how the shore station would compare to the inland station when
working another farther inland station I don't know. But I think I'd put
my money on the one over or closest to the water. I think anything close
to the ocean or to salt march etc, would be very good. I've been down to
the beach quite a few times when running mobile. I know my car always
does extra well when I'm parked next to the water on the beach. I
remember one time I even threw a ground wire from my car into the water
to see if it made any difference. Didn't seem to hurt things, but wasn't
drastic. Seems I was already doing ok, just being over that good ground
area. MK

wrote:

>The gain of a 4 meter dish is 10dB???

The physical are of a 4 m dish is 12 mï¿½ and the effective capture are
for is about 5 .. 8 mï¿½ depending illumination and other factors.

The capture area for a simple free standing dipole is about 0.13
square wavelengths.

On 2 m wavelength the capture area of the free standing dipole is
about 0.5 mï¿½, on 70 cm about 0.06 mï¿½.

The dish gain on 2 m would thus be 5 mï¿½/0.5 mï¿½ = 10 or 10 dBd,
on 70 cm 5 mï¿½/0.06 mï¿½ = 78 or 19 dBd.

The ground quality is much more important for vertical antennas than horizontal ones, so it would be misleading to make a blanket statement covering both. In the case of most horizontal antennas, there's no ground connection, so no current returns through the Earth, and the ground conductivity doesn't impact efficiency. For ground-mounted verticals, especially ones much less than a half wavelength high, the ground conductivity directly affects efficiency, and a radial system is generally used to increase the effective conductivity. Ground also has another, quite distinct, effect on both horizontal and vertical antenna patterns -- but it's different for each. An antenna's elevation pattern is formed by interference between the signal radiating directly from the antenna and one reflected off the ground. This reflection (which is actually more complex than a simple reflection) takes place within a few wavelengths of the antenna, or closer, depending on the antenna height and elevation angle being considered. Horizontally polarized waves are relatively insensitive to ground conductivity as far as reflection is concerned, except at very high angles. So ground conductivity can be important when designing an NVIS system with a horizontal radiator, but not for long-haul communications. Vertically polarized waves are another story. For these, typical ground conductivity leads to a severe attenuation of low angle signals due to the nature of the ground reflection. Only with very high conductivity ground, like salt water, will the elevation pattern approach the idealized perfect-ground pattern so often seen in books. Over most typical grounds, low angle radiation will be much poorer. These effects can easily be seen with any of the available modeling programs.

The bottom line is that a horizontal antenna won't benefit much by being close to salt water (unless very high angle radiation is the goal). Vertical antennas will benefit a great deal. I can easily believe the figures Mark quotes, provided that they're for a vertical antenna. I believe that anyone fortunate enough to have salt water, either ocean or marsh, within a few wavelengths of his antenna should take advantage of its high conductivity by using a vertically polarized antenna.

2886. Re: Need help on exam questions in E9C

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-21 00:00:00 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <39C9B872.E8483F35@eznec.com>
Source record: 180078

For two identical vertical elements with equal magnitude currents and
identical current distribution over perfect ground, the field strength
at the horizon will be

2*E1*cos((s/2)*cos(phi)+A2/2) where

E1 is the field strength from a single element (*)
s is the element spacing
A2 is the phase angle of current in element 2 relative to element 1
phi is the azimuth angle

Notice all the qualifications. Relieving any of them will complicate the
formula. A good reference is the "Medium-Frequency Broadcast Antennas"
chapter of Johnson, _Antenna Engineering Handbook_, or earlier editions
edited by Jasik.

Roy Lewallen, W7EL

(*) This isn't necessarily the field strength from a single isolated
element with half the input power. Mutual coupling will generally modify
the field strengths from the elements, resulting in a different value
from each when in the array than when isolated.

Ed:

Believe it or not, I agree with your entire post.

The point is that the data that has been presented by NC/Chip/Phil/Dr Nathan Cohen PhD/et al is only, to use your words, a first approximation. There is alot more data that could be presented that would give us a better idea of the antenna's performance than the little bit that has been allowed out.

I've been asking for more, and better data, and the Fractenna's have not been forthcoming with that data. Yes. there is one comparison between the FQY and a dipole.

I also agree that 3 dBd is an improvement over a dipole, and the F/B has merit as well. The problem, and the reason I've asked for a comparison between the FQY and any other Yagi, is that the F/B data, and the side and rear rejection data is not apparent. There is no way for us to extrapolate that data from a dipole:FQY comparison. Therefore, there is no way to compare the merits/caveats, other than the forward gain and the reduced form factor, of using the FQY over a full sized Yagi tuned for the same frequencies.

I thought I had made my intent in this clear, but reading back, I see I did not. My mistake, there.

-SSB

On or about Wed, 20 Sep 2000 17:47:29 -0400, "Ed Hare, W1RFI" <w1rfi@arrl.net>, using the forum rec.radio.amateur.antenna did say:

:sideband <sideband@cac.net> wrote:
:
:> Dipoles vary, as do all antennas. A dipole tested at one site will
:> perform slightly differently at another. Two different dipoles at the
:> same site will perform slightly differently than each other.
:
:Yes, to a relatively minor degree, but yes. This is why the term dBd has a
:half-wave dipole in free space as the reference antenna. If a dipole tested
:at one site will perform slightly differently than another, then the same
:thing could be said for the Yago or other reference antenna you are asking
:him to compare his antenna to. If the testing really were done on a
:calibrated antenna range, most of those site differences would be calibrated
:out. On a calibrated range, one can either apply power to an antenna,
:measure the field or power density at a particular point, and calculate the
:gain from that measurement (in that azimuth/elevation direction) or can A/B
:compare the measured power density against a reference antenna on the site

:(that presumably has very well documented performance). That is my general
:understanding of the subject; I am sure there are some on this NG who can
:add a lot to that generalization.
:
:> It is the convention, yes, and it gives a certain set of data, yes.
:> And that data is used to compare antennas, yes. But, as stated before,
:> dipoles vary. Conditions at testing locations vary. Ground varies.
:
:Which is why ONLY testing done at a calibrated antenna range can be seen as
:reasonably accurate. Modeling can be reasonably accurate too, to the extent
:that the model matches the conditions under which the antenna will be
:installed, or at least matches some reasonably agreed upon standard set of
:conditions. For the basis of comparing antennas, average ground conditions
:are usually acceptable as a reasonable basis for the model. The patterns
:that Chip has posted appear to have been modeled under those conditions, so
:I accept the results as a good first approximation of the performance of his
:antennas.
:
:> So what exactly are you afraid of? This comparison between your Yagi,
:> and any other Yagi of the same frequency range will only serve to show
:> the merits of your rediced form factor design. I don't see what the
:> big deal is here.
:
:Then make the comparison; take the modeled gain figures of any Yagi, convert
:them to dBd and do the subtraction.
:
:> Or is it that you don't want the world to know that in your FQY all
:> they're getting is something that's only slightly better than a
:> dipole, and directional?
:
:If 3 dBd is "slightly better" than a dipole to you, then that is what you
:can infer from the data published on his page. But don't discount the value
:of "directional." Although that 3 dB won't make much difference on transmit
:with strong signals, that F/B can make quite a difference on receive (I
:would be curious to know how much that F/B varies across the 10 M band,
:though -- at least across the CW/digital/voice/FAX portion of the band; that
:is why I was hoping to get a NEC model. If any of you have typed it in from
:the dimensional data on the page, please email it to me; I just don't have
:time to input the data.) Not only will you not hear the signals off the
:sides and back, more important, you won't hear noise (local or atmospheric)
:off the sides and back, giving an improvement on receive > 3 dB in the
:resultant S/N. On receive, I would take 0 dBd gain and 25 dB F/B over a
:dipole any day.
:
:And, in reality, the gain of 3 dBd for that 10M quad looks to be reasonable,
:and it is presented in a way that is relatively straigthforward.
:
:I really don't see what the beef is wrt the antenna's performance claims.
:
:73,

A wire to the sea from a car parked on the beach will not
have much effect. The very low resistance contact with the
sea will be nullified by the high wire reactance. Very
little current will flow along it.

Only by parking in the sea will you obtain any benefit.

Reg.

The term dBd does have legitimate uses, if the scenario is defined, for example comparing a dipole at 60 feet with a 3 el Yagi at the same height and same location. Those who *suggest* this are not *proclaiming long and loud*. This kind of ridicule is not needed or deserved.

Yes, the Beverage improves S/N ratio on receiving because it is
directive, but it does so at the expense of overall signal level. It
is a negative gain antenna, but with fair directivity.

I think 3dBd is probably a reasonable gain for any half-size antenna
loaded with a reasonable form of loading.

I guess there is so much noise accompanying the good data that it gets
lost in the background. Thank's for reminding us Ed.

The randomness of which I speak is in regards to the shape of the antenna.
I modeled the performance of the MI2 Fractal Loop as a baseline. Then,
using the same
total wire length as in the MI2 I created a random shape within the same
physical aperture as the MI2. The performance characteristics of both
antennas are
essentially the same.

Congrats to Sarah for placing second in the CS Science fair (silver medal in Electronics category)! Sara did a study on improving performance on a 'quadgi' by using fractal elements.

I corresponded with her dad in the Spring. She's worked very hard and done a great job!

Sara got some folks at TRW to volunteer some chamber time to corroborate her range measurements.

As a professor, I am very gratified that young people have seen how useful, accessible, and rewarding it is to explore fractal antenna technology. As with Sara, I encourage all hams to experiment with this exciting new technology!

As for QST, which put Sara's pix in the UP FRONT section of the October issue, it sure is surprising ! The last they dealt with fractal antennas--I submitted a manuscript to Technical Correspondence in Feb 1994-- I had Marc Wilson (K1RO) and Paul Pagel (N1FB) denigrate me for submitting an April Fool's article!

Some April Fool's article! QST missed out on publishing the first fractal element antenna article!

And there lies a tale...

I have been asked by QEX (an ARRL publication) to submit a fractal antenna article. I have agreed to consider it under 3 conditions of my request:

1) that the editor suggest a particular design need;
2) that the article be peer reviewed;
3) that the original Feb 1994 manuscript be published as a sidebar.

If these terms are workable, then I will provide QEX with a manuscript at a future date.

Fractal-element antennas are covered by pending and extant patents. Radio amateurs are encouraged to build fractal antennas on their own on an experimental, non-commercial basis.

73,
Chip N1IR

Your earlier comments were:

>You certainly can make a beverage. however, you'll need to keep the antenna as
>straight as you can for best f/b .

That isn't true. Unless the antenna deviates a reasonably large amount from straight line, say twenty degrees, there is very little change in F/B with a "bend" in the wire. F/B ratio is set by the length of the antenna and the termination mismatch, more than any other factor.

Beverages are very non-critical. That is one of their main advantages.

>An inch or two droop isn't a problem for a
>beverage, say, 10 feet off the ground. But a 3 or 4 foot droop is.

That isn't true at all. A three or four foot droop in a Beverage ten feet off the ground results in unnoticable performance change. The claim a Beverage needs to be held "within an inch or two" is totally wrong. That would make a Beverage virtually unbuildable in the real world!

>Also, the
>performance will very much depend on the uniformity of the ground.

Uniformity in what way? Conductivity? Elevation? Texture?

All of that makes very little difference.

73 Tom

I thought this to be the case with your incorrect description of the helically wound antenna. Perhaps my initial description of the antenna was not clear. I thought the most recent description was better. Hopefully this post will clear up this issue for you.

>
> From what I have seen of the two antennas you described, here is my summary.

> similar; they are within about 1/4 dB.]
>

I do not recall confusing directivity and gain as I am quite clear on the definition of both. When I asked you what the efficiency of the MI2 antenna was, you would not give me an answer. Given this, I simply chose to model the two antenna configurations with lossless wire. This may not be an exact practical representation of either antenna but it does provide a valid baseline for comparison.

From a practical standpoint, I believe this baseline to be valid because both
antennas have the exact same total wire length and the same overall physical aperture. In your statements above, you specifically state that the directivity and gain of the MI2 are within 1/4 dB, so I don't see why this is such an issue for you. You should also note that the other performance characteristics determined from my NEC4 model of the MI2 loop almost identically match the performance characteristics presented in your Comm Quart articles

> 2) You mention a spiral design--which looks like you fit into a 1/8 by 1/8 wave

> form factor, but now is only 5 inches in size on 20M... You ascribe this
> antenna with a directivity that is the same as the MI2--and a higher
radiation
> resistance;note that radiation resistance is the non-ohmic real impedance
at
> the current max...
>

I did not say that the helically wound antenna was only 5 inches in size on 20M. I said that the diameter of the helical winding was about 5 inches and that the total wire
length in the antenna was about 1.5 wavelengths. The new helically wound configuration discussed in this thread is a bit different because I set the total wire length and aperture size to match that of the modeled MI2 loop antenna.

Definition of radiation resistance can be somewhat ambiguous. Your comment regarding radiation resistance and the current max is a text book definition based on relating the total power radiated by the antenna to the maximum current on the antenna structure. Radiation resistance can also be defined at the feedpoint terminals by relating the total power radiated by the antenna to the current at the feedpoint.

In practice, most antenna engineers don't get bogged down in the these definitions. The practical concern is the feedpoint impedance. It is generally acceptable to define the feedpoint resistance as being equal to the radiation resistance plus the loss resistance. The total power available for radiation is in fact the total power delivered to the feedpoint terminals. If the antenna is lossless, then the total power radiated will be the total power delivered to the feedpoint resistance, which then can be defined as the radiation resistance.

When the antenna structure has loss, our concern is really determining the antenna efficiency. We know that Ptotal = Pradiated + Ploss and the efficiency is simply Pradiated/Ptotal. Being consistent with our feedpoint definition of radiation resistance, Ptotal is the total power delivered to the feedpoint resistance, Pradiated is the power delivered to the feedpoint radiation resistance and Ploss is the power delivered to the feedpoint loss resistance.

>

I did run directivity correctly. If I include the component of ohmic loss I will end up with gain. This is the definition. I intend to include ohmic losses in the antenna and re-post the comparisons showing gain.

>
> On (2), you further call this "helically wound". Now I am VERY confused. Is
> this a 3rd antenna?? Are you referring to a flat spiral, or is it something
> else? Surely you do not expect a 3-D COIL to fit into a 2-D form factor...
>

Yes it is a third antenna. I have presented three antennas for discussion in this thread.

One is the MI2 Fractal Loop. The second is an antenna having the exact same wire length and aperture size as the MI2 but configured in a random (non-fractal) shape. NEC and GIF files of these two antennas have been presented to anyone who has asked for them.

The third is a helically wound antenna having the exact same total wire length (within 0.4 m) and aperture size as the MI2 Loop. This helically wound antenna has 16 helical turns on each side of a square perimeter for a total of 64 helical turns. The diameter of the helical turns is 5 inches.

For me, the 2D v 3D nature of the antenna is not an issue.

>
> The flat spiral so described will have a very low radiation resistance and a

Again, there is no confusion on my part regarding directivity and gain.

>
> I would like to give you an opportunity to recant your statement that you have
> an "arbitrarily chosen random design". This is surely wrong.
>

Why would I recant a statement that I believe to be correct?

> This says that one
> may choose any other random design and attain the same result.
>

This is essentially correct. The antennas presented in this thread have the exact same total wire length and aperture size as the MI2 Fractal Loop. The only difference is that the
wire is configured into a random (yet symetrical) shape. The performance of these antennas is not the exact same but it is similar enough to demonstrate that the fractal geometry of the MI2 loop is not the significant factor in ahiveing the described performance.

Just to illustrate the point, I ran another arbitrary shape with the exact same wire length as the MI2 loop (actually it is 11 cm longer - slight mistake) and the exact same aperture size. Performance is as follows:

1st Resonance: 15.389 MHz (MI2 is 15.749 Mhz)
Resonant Resistance: 26.4 ohms (MI2 is 28.4 ohms)
Directivity: 2.18 dBi (MI2 is 2.14 dBi)
2:1 BW: 1.1% (MI2 is 1.27%)

3rd Resonance: 27.863 MHz (MI2 is 28.65 Mhz)
Resonant Resistance: 11.4 ohms (MI2 is 19 ohms)
Directivity: 4.17 dBi (MI2 is 4 dBi)

Not exactly the same but close enough from my perspective of determining the benefits of fractal geometry.

> Is there yet another antenna: ''a "helically wound loop"? Did I miss this?

Yuri
While on one of my working trips to PR4 I stopped
the car at a cut out of a hill with a drop
of a couple of hundred feet with a view of the sea
about a mile away The land is very dry and mainly
coral type rock
. I called CQ and was immediately
inundated with a pile up from Europe, It was terrifying,
I could not hear individual calls and cheated by calling
letters out at random and some always came back.
Went up a mountain top to a rain forest overlooking
the whole island and cound not hear a thing over the static!
Maybe you should rethink the idea of making a better
station because the enjoyment index goes way down.

Hell, no!
I tried that in Miami Beach, "parked" brand new 85 Cutlass in the salt water, and the water ate the car in about 2 hours, wires disintegrated, engine rusted out. (It was an accident, my first and last time experience with /M/MM :-)

Let's not get off the real question: What is better RF ground (for verticals) ocean front location, or pure salt marsh (not half salt, half sweet etc.), or?

I am aware of salt water vs. inland, etc.
For those who have not seen work, experiences and results of 6Y2A Team Vertical bunch (Force 12) check their page
http://pages.prodigy.net/k2kw/

I am after finding "bestest" salt water conditioned ground and expanding on their work.

Public notice:
Fractenna scientwists opinions are not considered, they are way off the rocker, spare us your diatribes. I want practical experiences - results, measurements and not scientwiphic speculations or computer modelling results before I put on diving suit or galoshes and explore.

Thanks, Yuri, K3BU

One caution when laying out Beverages, if you have sloping hill, it appears that long beverages are counterproductive. I had abt 1500 ft beverages going down the hill and Sloper beat them (that was on 160). Second night I shortened them to 800 ft, ant they were "singing" - day and night difference. Your mileage may vary depending on terrain/ground conditions.

The best killer Beverage I have seen so far is VE1ZZ's NE one, going over the rocks and terminated in the salt water.

2915. 10M CONTEST CHALLENGE: K1KW, K3BU

Newsgroup: rec.radio.amateur.antenna
Date: 2000-09-21 00:00:00 UTC
From: fractenna@aol.com
Message-ID: <20000921111005.26586.00000022@ng-ch1.aol.com>
Source record: 180107

I wish to challenge in the spirit of constructive competition, K1KW and K3BU in the upcoming 10M Contest in December.

The category will be low power, phone only.

Use whatever antennas you want. I will use the 10M Fractal Quad Yagi seen on the ham page of:

http://www.fractenna.com

This antenna provides a unique combination of ease of construction, optimum performance, and dinky form factor. It is NOT MATCHED in performance, simplicty, and reliability by any other such small antenna in that form factor. None.

My objective is to show that the unmitigated bluster from these two individuals is not only silly, but not in the true ham spirit.

SO let's battle it out on the air and may the best operator/antenna combination win!

I've already ordered a voice keyer, and will use my binaural enhancement technology to make up for my declining hearing. Otherwise my operating skills, I betcha, are superior to both K1KW and K3BU, while their vast but wasted antenna farms will not prove useful in helping'em win~! Also, as fewer hams go in the direction of aluminum tubing beanstocks, someone needs to show that SMALL WORKS, FRACTALS WORK, and that the future is now.

What say, Chuck and Yuri?

73,

More crap and lies from Freak. Where is the proof fo your "superior" skill?
Name one record in the contest Troller?

Yuri outgrew QRP, low power, handicapped categories. Unless paralyzed by equipment or customs problems, he always goes with big boys, after world or other records. He will not lower himself to Freak's level of "competition".
Yuri is in pursuit of pushing the limits on the antenna, equipment and operating front and in setting the records to be the best of the best.
You want to compete on my level? You are welcome! Wanna make a bet you chicken?
You would be stomped with your Fractal N. Crap!

Go away!

I think you are full of hot air. Use it to compete with me in the 10M contest
and do something constructive with it.

Or are you SCARED to compete against me?

So what you are saying is that you feel that you are so superior that you feel threatened by this 'nobody' with a fractal antenna??

That, is, someone who you are convinced cannot beat you in a contest (because he can't operate?) and with an antenna that can't posibly work? Seems to me you are a WEE BIT unrealistic..not to mention insulting to thousands of other hams.

Or is it just that you can't condescend to compete with someone who represents a more realistic cross section of HF operators?

Explain that (this should be juicy news going through the grapevine!)!

We really want to know:-)

Personally, I don't think we need any software designed especially for
spamming newsgroups worldwide.

Thanks, but no thanks.

Curt Breneman wrote:
"We can`t compare a long wire a large fraction of a wavelength above earth to a Beverage .05 WL or less above earth!"

Depends on earth composition under the wire. Some is like glass. Some is like salt marsh. Most is in-between.

The function of a radio antenna is to launch or capture a signal well. Directivity is often desired. Directivity concentrates a transmitted signal which increases the effective radiated power. Directivity concentrates received carrier power (reciprocity prevails) which improves signal to noise ratio.

Wavelengths which are long when compared with our surroundings require large antennas to produce directionality. At the longer wavelengths (lower frequencies) the Beverage antenna has proved economical and effective, especially for receiving, where efficiency is not so important.

The Beverage is directionally effective, economical, and easy to build and maintain. Like most effective antennas, it requires a lot of space. It is especially competitive at low frequencies where many alternatives become extremely large and usually require a lot of height as well as horizontal space.

Best regards, Richard Harrison, KB5WZI
